. INTRODUCTION

The year's activities included planning and executing a bagging program, compiling returns from two tagging programs, and catch sampling for age and marked fish composition. Other activities were interspersed and are detailed below.

MEETINGS ATTENDED

The more important meetings attended by one or both troll salmon staff members are listed in Table 1.

Table 1. Principal meetings attended during 1960.

Title	Place	Those attending
1. PMFC Technical Staff 2. Annual PMFC Meeting 3. Salmon Abstention Case 4. Pacific Fishery Biologists 5. OFC Policy Conference 6. Marine Sport Fishery Study 7. Project Leaders Meetings	Portland Portland Portland Lake Wilderness Astoria Portland Portland	Loeffel, Ellis Loeffel, Ellis Loeffel Ellis Loeffel Loeffel Loeffel

Preparation for these meetings consisted primarily of being able to discuss the subject at hand except for the presentation of a status report of the Pacific Coast troll salmon fishery at the annual PMFC meeting.

REPORTS SUBMITTED

Reports prepared and submitted during the year are listed below:

- "Oregon Fish Commission Cruise Report, Salmon Tagging Cruise, March 15-April 14, 1960."
- 2. "Status of the 1960 Ocean Salmon Fishery and a Review of Fast Landings." (Published in Thirteenth Annual Report of the Facific Marine Fisheries Commission for the Year 1960.)
- 3. "Proposed Program for Troll Salmon Investigations,"
- 4. "The Effect of Confinement on Blood Levels in Chinook Salmon and Coho Salmon." (Submitted for publication)
- 5. Summary of Troll Salmon Activities for the Biennial Report.

PERSONNEL

Bob Ellis was transferred to the Columbia River Fishery Development Program to work on a contract study. His replacement was not named during 1960. Temporary or seasonal help employed during the year is summarized in Table 2.

Table 2. Temporary help employed during 1960.

Wame	Starting date	Terminating date
Robert Erwin	3-14-60	5-5-50
William Hess	5-9-60	5-13-60
Robert Gretzner	6-14-60	9-12-60
Robert Rohland	6-17-6 0	9-27-60

EQUIPMENT PURCHASED OR CONSTRUCTED

Two "anethetizing" boxes were built from fish shipping boxes. The dimensions are approximately 40 x18 x12 inches. A tagging cradle was also constructed.

PROCEDURE FOR MAKING CURRENT CATCH ESTIMATES

Additional ocean mark samplers were assigned to the investigation in 1959 and 1960 to provide better coastwise coverage. A sampling level of 20% of the catch was set as the acceptable minimum. In order to observe this minimum, knowledge of the magnitude of the catch had to be obtained concurrently with the sampling data. Official catch statistics are not available until well after the termination of the fishing season necessitating the development of a system for estimating the catch on a current basis. The solution taken was to compute estimates from partial statistics obtained from key buyers, weighted by the importance of these buyers in the area in question during the previous season. Week and PMFC zone were considered the smallest practical work units. Estimates of this type are

attainable by Thursday of the week following the catch period under study which is soon enough to permit two or three reviews of progress within a month—the time unit used in mark sampling and analysis. Cumulating the weekly records provides an estimate of the total season catch by zone and date.

The accuracy of the catch estimates can only be determined by comparison of the estimates with official statistics over a period of years. However, their reliability increases with each additional set of records used in making the weekly estimate. To this end all readily attainable records were utilized, providing about 70% complete reporting.

In practice the company offices were visited and the landings obtained by species and size group. These were totaled by FMFC zone and expanded by dividing the landings by the appropriate factors. The estimated total landings were divided by average weight values obtained during the period under study, yielding numbers of fish. Additional totaling made comparison with the number of fish sampled possible. The computational form used is shown in Table 3.

Table 3. Example of ocean mark sampling summary form.

Subordinate headings for Newport and Coos Bay are identical with those for Astoria. In practice entries are made in all blanks.

2/ Large, medium, and small size groups, respectively.

The landing records received serve also as a means of breaking the official catch records, which do not provide catch values by size group, into these categories. This permits sampling average weight data that is collected by size group to be applied directly and should impart greater accuracy to the estimate of total numbers of fish in the catch.

PROCEDURE FOR ESTIMATING THE AGE COMPOSITION OF THE TROLL CHINOCK CATCH

Prior to 1960 annual estimates of age composition of the Oregon troll chinook catch were not made. One of the reasons was the difficulty in securing representative samples for all PMFC areas (hereafter referred to as port) for the important months of the season. This barrier was effectively removed when samplers were assigned to Coos Bay and Newport for most of the 1960 season.

Information on the age composition of the catch was needed to determine the predominant age(s) at which the stocks were being harvested and to detect changes in the age composition between years. Eventually this information may facilitate detection of weak or strong year classes entering the fishery and permit observations on the health of the stocks.

The ambitiousness of the present program is limited by the staffs ability to collect and read the scales used in age determination. It is further restricted by the frequent occasions on which the fish in the catch are only partially available for examination.

The procedure follows that of Gulland (1955). The catch is stratified into three weight groups and the age composition of each group estimated separately. The weight groups in question are those of the industry,
viz., small—less than 8 pounds dressed, medium—8 pounds to 12 pounds, and
large—12 pounds and over. Scales are taken from five randomly determined

fish per size group per port per day (normally five days per week). Randomness is attempted (but perhaps not achieved) by consistently taking the
samples from the first five fish available to the sampler as he approaches
a container of large, medium, or small salmon.

The daily samples are placed in prenumbered positions on a gummed 3 x 5 card. Numbers 1-5 indicate small salmon, 6-10 medium, and 11-15 large. The card is in turn numbered with the last two digits of the year of collection followed by its serial ranking within the year. Consequently scales from each fish receive a unique number. A catalog is kept which shows by card number, the date, place, and number size group of all daily samples.

Age readings are made with reference to the individual sample number only. Independent first readings are made by two readers. Readings resulting in disagreement are repeated again independently. Samples upon which aging disagreement still remains are submitted to a third reader. His agreement with either of the second readings determines a final age. Samples still unresolved are assigned to a non-ageable category. Regenerate samples are also assigned to this group.

The age data is then tabulated by size group, by card number for each port-month unit and totals derived (Table 4). From this summary the sample percentage age composition for each port-month unit can be determined.

The percentage sample age composition is applied to the appropriately subdivided annual landings. Month-port totals by age group are obtained (Table 5). These in turn are summarized to provide the number by age group in the annual catch.

Weaknesses in the procedure include: (1) method of selection of individual fish to be sampled; (2) the fixed five fish size of the daily size-group sample instead of proportional sampling; (3) the disproportionate sampling between size groups; (4) the age determination method; and (5) validity of the landing breakdown into catches by size group.

CATCH STATISTICS FOR THE 1959 OREGON TROLL SALMON FISHERY

The 1959 catch statistics, received in June 1960 from the Portland office were summarized in the usual manner and are presented in Tables 6 and 7 for chinock and coho, respectively.

The total Oregon chinook catch of 532,000 pounds (636,000-104,000 pounds landed in Washington) was the poorest since 1943. The decrease was more severe at the Oregon coastal ports than at the Columbia ports. The Coos Bay and Newport areas were both 22% of average for the period 1950-59. Columbia ports were 57% of this average. Only in the Columbia area did the 1959 catch approach 1958 (67%). At Newport and Coos Bay the 1959 landings were only 31 and 22% of 1958.

The 1959 Oregon coho catch was 1,004,000 pounds (total--Washington Columbia River ports + miscellaneous) which like the chinook catch was the poorest since 1943 (Figure 1). This follows only two years behind the high silver catch made in 1957. The abruptness of the decline suggests adverse fluctuations in the environment rather than fishing as the cause. Landings at all PMFC areas were below the 10-year average with Newport (36%) exhibiting the greatest decline Chinook and coho landings combined were also the poorest since 1943.

THE 1960 ORECON TROLL FISHERY

General comments

Poor fishing weather greeted the fishermen at the opening of the season. Landings in the Astoria area were good in late April but very poor in May. Early landings at the coastal ports were good when the weather permitted fishing. Bad weather hampered fishing in portions

of July and August. Nevertheless some good chinook landings were made in late July and early August with the fish coming from the Bandon and Heceta Head areas. The August chinook landings were characterized by good numbers of large fish.

Poor coho fishing prevailed in the fisheries north of the Columbia causing prices to be high. The seasonal maximum on the Seattle board was \$.61 per pound for silvers and \$.95 for chinook. Oregon fishermen, of course, benefited from these better than usual prices.

Estimated catch

The current catch estimating procedure employed for the first time during the 1960 fishing season proved to be acceptable in basic design. Landing record copying and computing consumed about one man-day per week. Landings were collected on a two-week basis for one Newport company due to the lack of a permanently assigned sampler at that port. Records for the other Newport buyers were obtained at their Astoria offices. Sampling at both Coos Bay and Newport was spasmodic in April, May, and September which resulted in low mark sampling intensities and less frequent catch estimates.

Tables 8 and 9 present the estimated 1960 catch as compiled through the end of September. Landings are shown by species by PMFC zone in pounds (dressed) and for the entire state in pounds and in numbers of fish. The Columbia River area catch includes estimates of landings made at the Washington Columbia River ports of Ilwaco and Chinook which amounted to about 45% of the chinook and 60% of the silvers landed in the Columbia River area. These figures indicate that Oregon chinook landings were approximately 1.6 million pounds or three times the 1959 figure. Estimated Oregon coho landings were near 1 million pounds.

RESULTS OF 1959 SAMPLING

Mark sampling

A mark sampler was stationed at Astoria from April to September and at Newport and Coes Bay (Charleston) from June to September. This sampling effort resulted in 11.4% of all chincok landed and 15.5% of all coho landed being sampled for marks. This level of examination was somewhat lower than desired and was the product of several factors, viz. (1) the reduction on the amount and importance of Charleston landings; (2) the late start, mid June, of the Charleston sampling; and (3) the low volume landed which led to quick disposal of the fish before sampling was possible. The sampling information and mark recovery ratios are presented in Tables 10 and 11 for chincok and coho, respectively. Using this information a calculated number of recoveries by the fishery of each double fin mark was obtained (Tables 12 and 13). No chinook mark was observed in abundance and only three were recovered more than twice. Coho marks were more commonly encountered with 140 actual recoveries of one mark, 1956 brood Klaskanine, occurring. This mark occurred regularly in all areas and months of sampling. In addition to the double fin marks recovered, 114 single fin marks were found in 1959.

Average weight sampling

Average weight data obtained from sampling the catch is presented in Table 14 for both chinook and coho. Unweighted averages of the data for port, month, and season are shown as are the month and seasonal catch-weighted averages. The chinook catch-weighted average weight for the season was only 8.45 pounds dressed. This is the weight equivalent of 27-inches fork length which calls attention to the small average size of the chinook now taken in this fishery. When it is remembered

that fish making up the spawning runs of this species seldom have an average size of less than 15 pounds the loss of potential growth in ocean harvest ing is apparent. Equally distressing, but maybe less avoidable, is the 5.0 pound dressed average weight of coho in 1959. Comparison between these sampling data and those from prior years (1956-58) shows the 1959 coho to be 14% smaller. The small size in this case is more likely related to poor growing conditions.

CATCH SAMPLING OF 1960 FISHERY

Mark sampling

The 1960 season was a more prolific producer of marks than 1959. This was particularly noticeable for chinook which increased from 45 in 1959 to 263 in 1960, a change that is probably attributable to the increased landings and changes in numbers of marked fish released more than to increased sampling effort. Table 15 summarizes the recoveries of both chinook and coho showing all marks recovered by month of recovery. Two chinook marks showing most frequently were the adipose-left maxillary and adipose-right maxillary from OGC Rogue and Umpqua spring chinock releases. Fish bearing these marks were from the 1956 or 1957 broad year.

About 23% of the chincok and 13% of the cohe landed during 1960 were sampled for marks (Table 16). This rate was not constant throughout the season being particularly low for chincok in May and for cohe in August and September. The cohe decline was the result of shifting emphasis to chincok sampling as these landings picked up in July and August.

Scale collection

Although the troll chinook season opened on April 15, scale collection did not commence until the landings increased towards the end of April.

The first samples were taken from the Columbia River area fishery, but by May sampling was conducted at several ports along the coast. The previously

described procedure calling for scales from five fish from each size group per day per zone (Columbia R., Newport, and Coos Bay) was followed. One-hundred and eighty daily samples were taken which involved scales from 2,177 fish (Table 17). The number of scales collected by size group varied little within the zones and only moderately between zones. No difficulty was experienced with this procedure for collecting scales except for the times when sufficient fish were not available and the five per size group could not be collected.

Plastic impressions of the scales were made using the OSU Scafoods Laboratory press and were completed by December. Reading of the scales had commenced by them also.

SPRING TAGGING PROGRAM

Program outline

Preliminary results of the 1959 March-April tagging program were presented at the 1959 PMFC meeting in San Francisco. It was decided to repeat the experiment in 1960. The program like the first one was to be FMFC sponsored and conducted jointly by the Oregon Fish Commission and the Washington Department of Fisheries. Subsequently, a detailed 6-page outline of program plans and procedures was prepared by this investigation and reviewed with WDF staff members.

There were two general goals. The first was to catch chincok to measure abundance, age composition, spring and fall stock contribution, and compare barbless vs. barbed hooks. The second was to tag and release fish to determine quantitative contribution by stream of origin. Recovery distribution by fishery was also of interest.

Results of 1960 tagging

Detailed results of the Oregon field work are available in the cruise report. Briefly stated the results were as follows. The Whisper skippered

Table 17. Log of 1960 troll chincok random scale samples-

Month	No. of			Numb	er of	scales	/size	group			Total

by George Crishaber was chartered for the period March 15 to April 15.

Fishing was done on 14 days near but north of the mouth of the Columbia River.

Two hundred and seventeen chinook were caught of which 157 were over the minimum commercial length of 26 inches. A total of 194 were tagged and released.

Washington's results were similar.

Tag returns were from ocean and river fisheries from hatcheries and from natural spawning runs. The 1960 total Oregon tag return of 53 (27%) is summarized in Table 18. Recovery data was entered on "Rocket" punch cards as received.

Table 18. 1960 recoveries of chinook tagged in the 1960 spring tagging program by gear of recapture.

Gear of recapture	Number
Opens two?! Fishows	71
Ocean troll fishery	\mathcal{U}_{p}
Ocean sport fishery	16
River gill-net fishery	15
Hatchery	6
Spawning migration	Å
River sport fishery	9
Total	53

Second year returns of 1959 tagging

Six recoveries were received in 1960 from the 1959 Oregon tagging. Four were taken in the ocean fisheries (two each troll and sport) and two in the Columbia River gill-net fishery. No hatchery or spawning ground recoveries were made. The 2-year recovery of 94 is 30% of the tagged fish released.

DATA FOR CALIFORNIA

Oregon 1959 catch statistics for chinook and coho were summarized and sent to California. The calculated number of California marks (fin clips) recovered by the Oregon troll fishery was determined from sampling information and sent to California.

PLAN FOR MARINE SPORT FISHERY STUDY

Public Law 359 enacted in 1960 authorized appropriation of seven million dollars for research on marine game fish. The money was to be spent through the Department of Interior with some passed on to the states. Oregon, Washington, and California anticipating receipt of some of the funds agreed to prepare individual plans of study—that would be integrated into a single plan under PNFC auspices.

The PMFC administrator prepared a general outline as a guide to the states. The Coastal Rivers and Troll Salmon project leaders were charged with developing an Oregon plan from the PMFC guide. Consideration was initially given to inclusion of all species—salmon and non salmon—taken by the sport fishery, but the plan first submitted was for salmon alone. The general study phases included were:

- Estimate of the salmon sport effort and catch per unit of effort by species by area.
- 2. Evaluation of age composition and maturity.
- 3. Determine mortality of released sport-caught fish.
- 4. Study origin of salmon stocks taken by fishery.
- Study of gear and methods.
- 6. Develop methods to increase productivity.

FATIQUE-MORTALITY

Determination of chinook and coho blood-lactate levels in samples taken during late 1959 were completed in 1960. The data gathered in this two-year study to observe the mortality induced by fatigue were analyzed and the results presented for publication in the draft of a paper entitled:

"The effect of confinement on blood levels in chinook salmon and coho salmon."

Publication will be in the Fish Commission Research Briefs.
