26	Pink shrimp sex composition (% male, transitional and female), sample size, and number of primary females during April, September and October from Oregon state statistical areas 18-32, 1989.	34
27	Annual United States and Canadian Pacific coast landings of pandalid shrimp by state and province (millions of pounds).	35
28	Number and percentage of vessels by gear type for vessels landing pink shrimp into Oregon ports, 1957-1989.	36
29	Pink shrimp catch (millions of lb), effort (hours=sre) and CPUE for shrimp landed in Oregon, 1968-1989.	37
30	Numbers of pink shrimp (billions) and percent age harvested in Oregon state statistical areas 18-28, 1966-1989.	38
31	Fishing effort (single-rig equivalent hours) for pink shrimp in the coastal waters of Washington, Oregon and California north of Cape Mendocino, 1966-1989.	39
32	Average count per pound of pink shrimp from Oregon state statistical areas 18-28, 1966-1989. Counts weighted by area-month catches.	40
33	The number of pink shrimp deliveries by month into Oregon ports: 1979-1989.	41
34	Average ex-vessel price of pink shrimp (<i>Pandalus jordanii</i>) and average ex-vessel price adjusted for inflation (in constant 1977 dollars, based on GDP deflation), 1978-1989.	42

INTRODUCTION

The data summaries presented in this report extend the time series of Oregon commercial pink shrimp data produced by Saelens and Zirges (1985). Detailed statistics on pounds landed, effort, age composition, count per pound, and sex composition of shrimp landed in Oregon are presented for each year from 1985 through 1989. Longterm landing statistics are presented from Alaska, British Columbia, Washington, and California. Longterm effort statistics are presented from California and Washington. Changes and conditions which occurred in the pink shrimp fishery from 1985 through 1989 were described and discussed by Jones and Hannah (1992).

METHODS

Catch and effort statistics by month and state statistical area were summarized from trawl logbooks, landing tickets, and biological samples (market samples) collected at seafood processing plants. Both single-rig and double-rig effort is reported in single-rig equivalent hours (SRE) and will be referred to simply as "hours" in this report when no other distinction is made.

Each month during each season, we attempted to collect 4-6 market samples of approximately 100 pink shrimp from each area (Figure 1). Samples were obtained at the docks. We counted and weighed the shrimp to determine count per pound (count), and measured each carapace length. During April, September, and October, each shrimp was classified as male, female, or transitional based upon close examination of the inner ramus of the first pleopod after Tegelberg and Smith (1957).

We combined data from individual samples within a month and area for analysis of age composition and sex composition. Raw length- and sex-frequency data were rescaled proportionally to a sample size of 100 before they were combined with other samples when sample size deviated substantially from 100 shrimp. Hence, samples were given equal weight in determining age and sex composition.

We determined age composition for each month and area by identifying modes in the combined length-frequency histogram. Ages were assigned to individual shrimp using nadirs in the histograms to set a range of carapace lengths corresponding to each age group. Sometimes a bimodal distribution of age-1 shrimp observed late in the season would complicate the analysis. In these instances, the bimodal distribution developed slowly from August through October and was easily recognizable. Mean length at age was calculated for each month and area after the age and sex of each shrimp was assigned.

We estimated catch and effort statistics by area for 1985 through 1989 using logbook and landing ticket data. Landing tickets provide a complete summary of catch, but no information on area of catch. Logbook data gave information on area of catch and also information on fishing effort and catch per unit of effort (CPUE), but was often incomplete. The pattern of catch and effort from the available logbooks was used to allocate the landed pounds and the associated effort to individual areas on a port and month basis. The exact methods used in 1985 and 1986 to obtain these estimates differed from those used after 1986. Logbooks and landing tickets were collected for all years, providing tow-by-tow data on date,

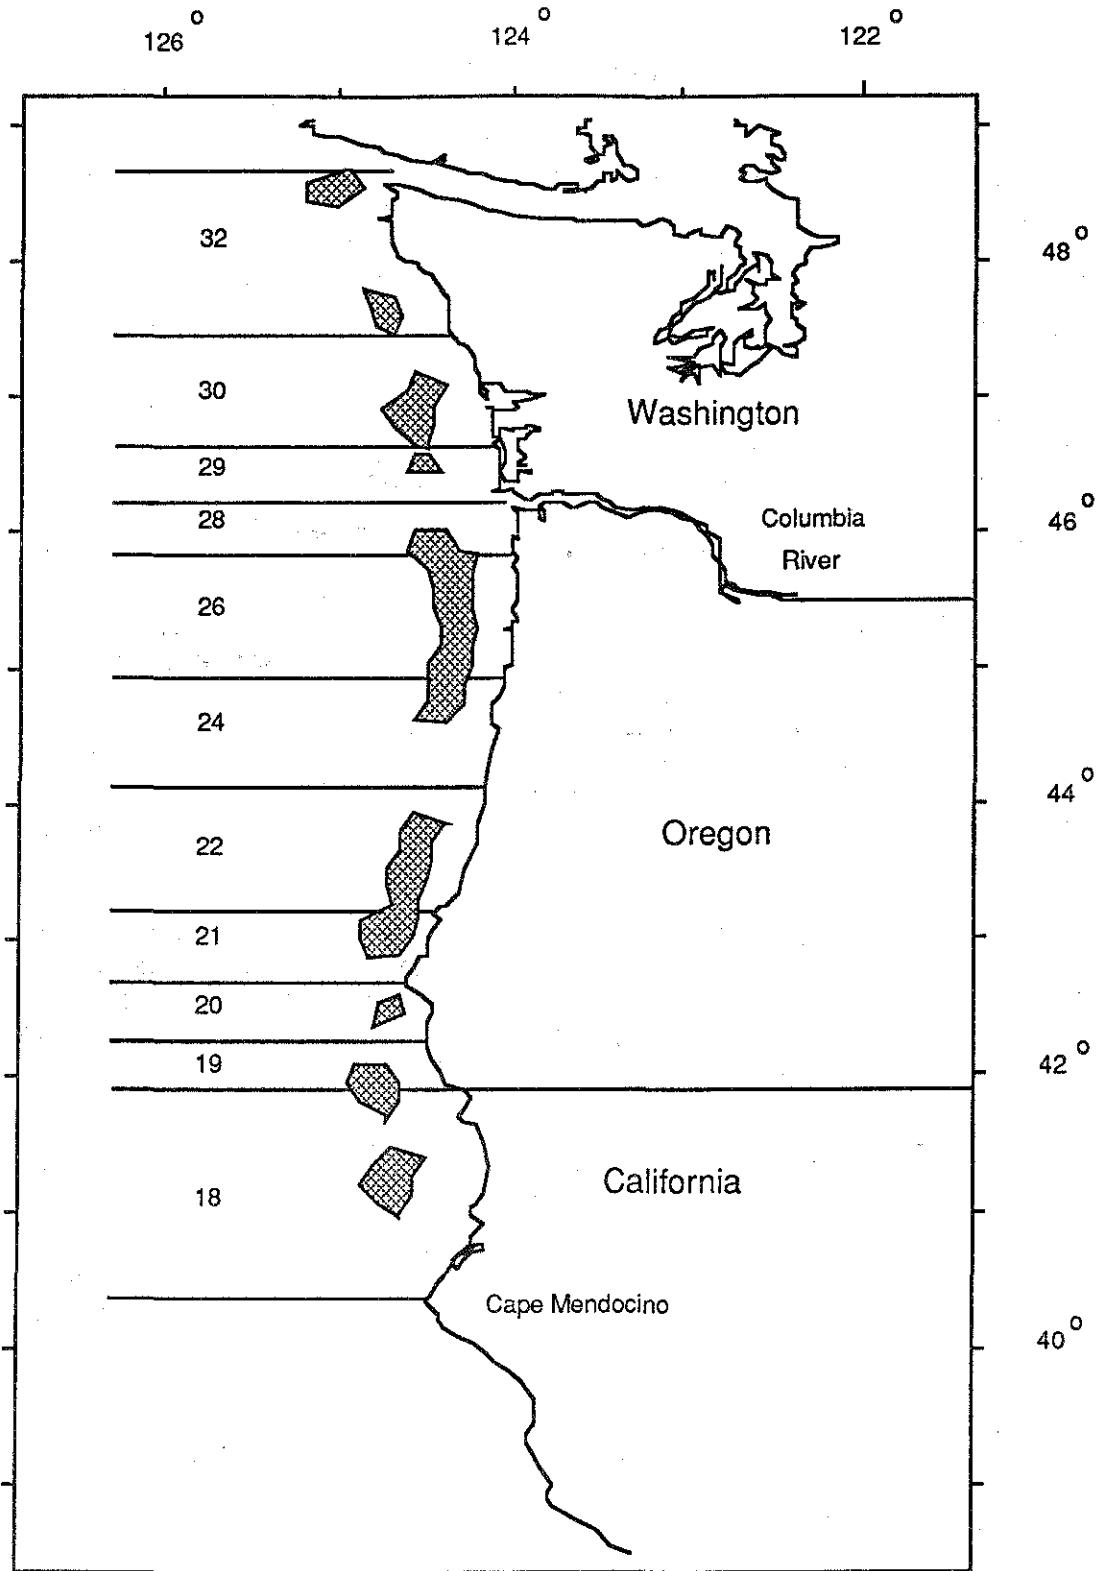

Figure 1. Oregon state statistical areas (18-32). Commercially fished pink shrimp beds along the Washington, Oregon, and northern California coasts are shown in crosshatching.

location, tow duration, hailed catch, and actual pounds landed. During 1985 and 1986, all landing ticket information and useable trawl logs were entered into a REVELATION® data base and expanded on a tow-by-tow basis. Single-rig and double-rig effort and CPUE were not expanded separately, but were standardized to double-rig equivalents (1 SRE = 1 single-rig hour = 1 double-rig hour X 1.6). Trawl logs were summarized by trip from 1987 through 1989 to provide hours fished and the pounds hailed for each area fished within a trip. Trawl log summary data and landing ticket information were then recorded on trip summary sheets and entered into a FOXBASE+/MAC® data base for processing. Trips whose hauls differed from the landed pounds by 50% or more were discarded from the data base. Poundage and effort was allocated by port to the appropriate area. Single-rig and double-rig effort were analyzed separately. Additionally, in 1987 and 1989, useable trawl logs were systematically subsampled at a 50% rate (100% for single-rig effort in north and central coast ports) because of the large volume of logs and limited staff time. Subsampling was not used in analyzing data from 1988.

Table 1. Pink shrimp landed catch (C=lb X 1000), effort (E=sre hours) and CPUE (C/E=lb/sre) by Oregon state statistical area and month for vessels landing pink shrimp into Oregon ports, 1985.
