OREGON STATE SHELLFISH PROGRAM 1987 BAY CLAM DATA SERIES REPORT

INTRODUCTION

This report is designed to compare and contrast information from the 1987 bay clam data series with previous years' data. This report summarizes the results of our bay clam studies conducted by the Oregon State Shellfish Program during 1987. Activities summarized include recreational and commercial clam fishery monitoring, hatchery stock enhancement, and natural recruitment studies. This report is presented as a series of tables and figures with a minimum of discussion; other reports will evaluate the data presented here. The tables and figures included give a historical overview of clam harvesting activities and are presented in a manner to allow future analysis to show trends or changes in stock status and fishing activities. This report is intended primarily to be an internal document, to be used as a reference by the shellfish staff.

RECREATIONAL CLAM FISHERY

Recreational clam digger interviews are conducted annually on each of the major clam harvesting tideflats of the Tillamook, Netarts, Nestucca, Yaquina, Alsea, Siuslaw, Coos, and Coquille estuaries. Interviews are usually conducted by two shellfish staff members. A count of diggers is made on each tideflat at low tide; this provides a peak digger count for that day. Currently, an effort is made to visit each tideflat at least two times per season, in the spring and again in midsummer. This is about half of the sampling effort that we expended annually from 1975 to 1984 to collect recreational use data.

We attempt to measure and age a minimum of 100 clams of each species for each tideflat. We measure the height of the cockle clam and the length of the butter, gaper, littleneck, and softshell clams. We age the various species of clams by counting annuli on the shell surface. The total number of annual checks is back-calculated to give year of recruitment.

Interview data collected included catch/effort, digger origin, species, age, and length composition. These data are presented for each tideflat in Appendix Tables 1-28. Table 29 summarizes the recreational activities presented in Tables 1-28 and Table 30 shows the peak counts of clam diggers taken at low tide for each of the surveyed tideflats.

In 1987, we interviewed 1,508 clam diggers that expended 2,154 hours of effort to harvest 25,313 clams (Table 29). The clam diggers averaged 16.8 clams/trip or 11.8 clams/hour.

Digging success was slightly poorer in 1987 than in 1986 when 17.7 clams/trip were taken. This decrease was influenced by poorer digging on several major clam beds in Netarts, Yaquina, and Coos bays. Since 1977, when the Commission approved a reduction in bag limit from 36 to 20, clam digger harvest has ranged between 14.7 and 18.8 clams/trip. In 1976, prior to the reduced bag limit, clam diggers averaged 20.9 clams/trip.

As in previous years, most clam diggers traveled some distance to harvest clams. In 1987, 35.6% of the diggers were local county residents, 53.4% were from Oregon but living outside the county of harvest, and 10.9% were out-of-state residents (Table 29). These figures were generally the same as in 1986.

Since 1976, there has been a gradual increase in the percentage of local diggers participating in the fishery, whereas the percentage of out-of-state residents has remained nearly the same.

COCKLE HARVEST COMPOSITION

The cockle clam was the most frequently observed species in the recreational fishery representing 41.7% of the 1987 harvest (Table 29). Butter, softshell, and littleneck clams comprised 24.0, 15.3, 12.4, and 5.2% of the bag, respectively. These values fluctuate annually but the general trend shows a gradual decline in the gaper and softshell harvest and an increase in the take of cockle and butter clams. Littleneck clams have not shown a trend in the harvest. The reduced occurrence of gaper clams can be partially attributed to poor recruitment of this species in a number of our more popular clam beds, especially at Happy Camp in Netarts Bay.

Length composition data collected for each species shows a

gradual increase in mean size for the softshell since 1984, the butter clam since 1985, and the littleneck clam since 1986. Decreases in mean size were observed for the cockle clam since 1985, and the gaper clam since 1986 (Table 29). Data collected on length composition since 1979 revealed only minor variations in overall mean size for each species (Figure 1). Gaper, softshell, butter, cockle, and littleneck clams averaged 107.9 mm, 92.7 mm, 83.0 mm, 61.9 mm, and 53.2 mm in 1987, respectively.

Changes in digging effort through time as reflected by peak digger counts revealed a general increase in digging effort from 1986 for most of the surveyed tideflats (Table 30). The largest

increase in peak digger counts was observed for the North Spit on Coos Bay (83 to 158 diggers). There was no apparent reason observed for this increase in digging activity.

COMMERCIAL CLAM HARVEST

In 1987, we issued 121 permits to commercial fishermen to harvest bay clams. Of this total 34 reported landing 46,283 lb of clams (Table 31). This is about half of the 1986 harvest when 40 clam diggers reported landing 82,609 lb of clams. Of the total clams landed in 1987, 43.6% (20,202 lb) were cockles.

Tillamook Bay was the major producer with 81.5% (16,460 lb) of the total cockle harvest. Other clams harvested coastwide were littlenecks (14,140 lb), gapers (6,368 lb), butters (3,046 lb), and softshells (2,527 lb). The continuous decline in harvest of gaper clams since 1982, when 106,440 lb were taken, again illustrates poor recruitment of this species in several of our bays.

Tillamook Bay produced the most clams in 1987 with 22,936 lb reported (Table 32). Nehalem and Coos bays produced 10,723 lb, and 10,214 lb, respectively. Yaquina, Siuslaw, Coquille, and Alsea bays produced minor poundages of clams.

We collected age and length composition data for commercially harvested subtidal native littleneck clams in Nehalem Bay, cockle and littleneck clams in Tillamook Bay, gaper clams in Coos Bay, and intertidal cockle clams in Yaquina Bay. Figure 2 shows that the 1983 and 1984 year-class littleneck clams dominated the Nehalem Bay commercial harvest in 1987. The harvested clams averaged 40.6 mm in length. In 1986, the clams

averaged 41.8 mm in length. Cockle clams harvested subtidally in Tillamook Bay were primarily of the 1982 and 1983 year-classes (Figure 3). Six year-classes were represented in the harvest and the harvested clams averaged 62.8 mm in length. Littleneck clams were dominated by the 1982 year-class in the Tillamook Bay harvest (Figure 4). The clams averaged 48.1 mm in length. In Coos Bay, gaper clams harvested were primarily of the 1975 year-class and averaged 132.9 mm in length (Figure 5). Gapers harvested in 1986 averaged 130.8 mm.

We rarely encountered commercial fishermen harvesting clams intertidally. On one occasion we checked the commercial harvest of a fisherman in Yaquina Bay taking cockles for crab bait. The harvest was dominated by the 1985 year-class and the clams averaged 52.1 mm in length (Figure 6).

SPECIAL STUDIES

Hatchery Stock Enhancement

Tillamook Bay

No Manila clams were planted in Tillamook Bay in 1987. Clams planted in test plots in 1984 and 1985 were sampled for growth and survival. Table 33 summarizes the results of our Manila clam plants in Tillamook Bay since 1971. Of particular interest was the difference in survival of clams placed under Vexar netting as compared to uncovered clams. Covered clams showed a 15.0% survival of juvenile clams, 25 months after release, as compared to 0.3% survival for clams planted with no protection. Clams planted as adults in 1985 had survival rates

ranging from 52 to 90%, 26 months after release. These clams were planted without protection of Vexar netting.

Yaquina Bay

Manila clam set planted under Vexar netting near King Slough in 1985 revealed a survival rate of 72%, 20 months later (Table 34). These clams, 18.1 mm when planted, averaged 41.2 mm in length.

During 1987, we sampled each of the 14 test plots established in 1986 to determine if various introduced substrate materials could impact survival of Manila clam set (Gaumer 1990). Also tested was the impact of 1/2-inch Vexar netting on clam survival.

Preliminary results of our tests revealed that at the 95% confidence level survival of clams released under netting was not significantly different than for those left uncovered whereas substrate material did have a highly significant impact on survival of clams (Table 35). When comparisons in survival of clams were made between substrate types, highly significant differences were recorded especially for clams released in a substrate containing a combination of pea gravel and ground oyster shell (Tables 36-37). No significant differences in clam survival were realized for clams releases in any of the other sediments or combination of sediment types.

In 1987, we continued to release hatchery produced Manila littleneck clams in Yaquina Bay near King Slough (Figure 7). We placed an estimated 100,000 clams averaging 6.7 mm and at a

density of 100/sq ft under Vexar netting and 20,000 were planted with no protection.

Coos Bay

Table 38 shows the results of our Manila littleneck clam plants in Coos Bay since 1973. We sampled the 1984, 1985, and 1986 planted clams in 1987 and recorded survival rates ranging from 0.8% to 88.7%. The poorest survival (0.8%) was for clams

planted without Vexar protection near Valino Island. Clams released nearby under Vexar netting, produced a survival rate of 34.4%.

Natural Recruitment Studies

Yaquina Bay

We collected 11 subtidal dredge samples from an 18.4 acre area in Yaquina Bay in September 1987 to determine year-class strength, recruitment success, and population and biomass estimates (Figure 8). Each sample covered 1 sq ft of surface area; depth of samples averaged 12-14 inches.

The 11 samples produced 104 gaper clams (9.5/sq ft) that averaged 117.5 mm in length. No evidence of recruitment of gaper clams was observed nor were any 1979-86 year-class clams recovered from the area. The 1975 year-class continued to dominate the standing crop comprising 56.7% of the 1987 sample (Figure 9). We estimated that 7.6 million gapers, weighing 6.5 million lb, inhabited the area (Table 39).

Netarts Bay

In addition to the subtidal samples taken in Yaquina Bay, we collected five 1 sq ft intertidal samples in Netarts Bay to

samples determine recruitment success. Each sample averaged 3 inches in depth and was washed through a 3 mm sieve.

The five samples produced five 1987 year-class gaper clams (1.0/sq ft) (Figure 10). These clams averaged 5.7 mm in length. No evidence of 1986 year-class gapers was observed in the samples.

SIGN REPLACEMENT

In 1987, the shellfish staff continued a coastwide project of repairing or replacing regulation signs. We currently are maintaining 187 signs along the Oregon coast.

ACKNOWLEDGMENTS

I wish to thank Darrell Demory, Terry Link, Jean McCrae, Neil Richmond, Mark Saelens and Rick Starr for their assistance in gathering the data used in this report.

¹ Planted as adult clams.

² Planted under "Vexar" netting.

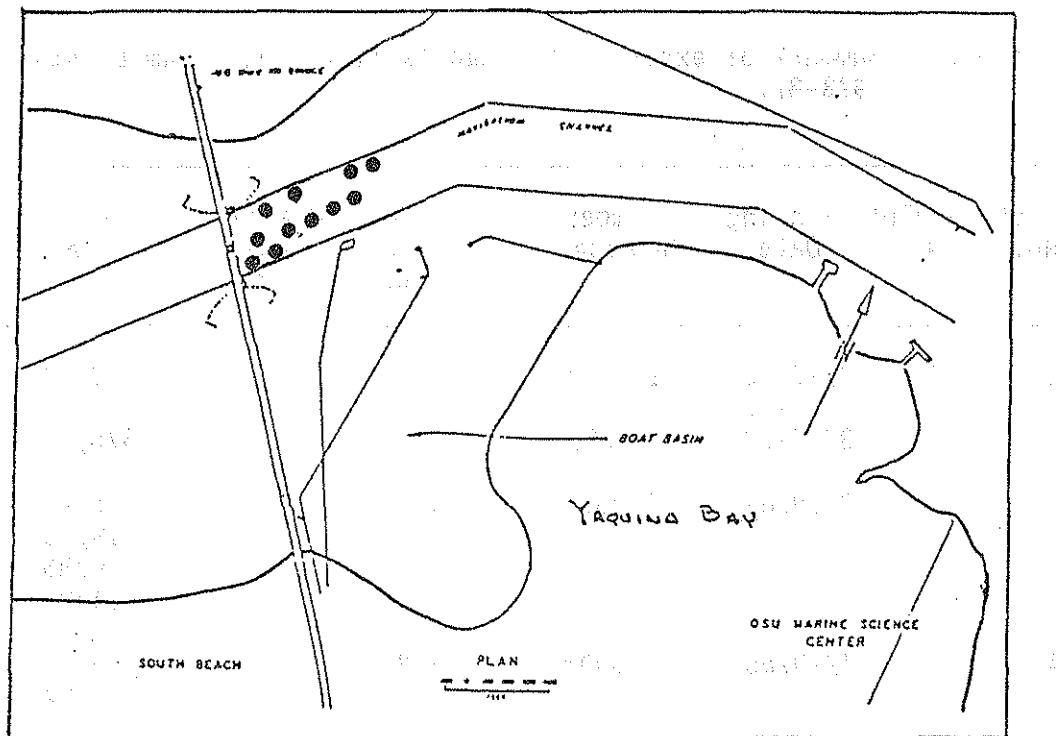

Figure 8. Subtidal clam survey area in Yaquina Bay, 1987.

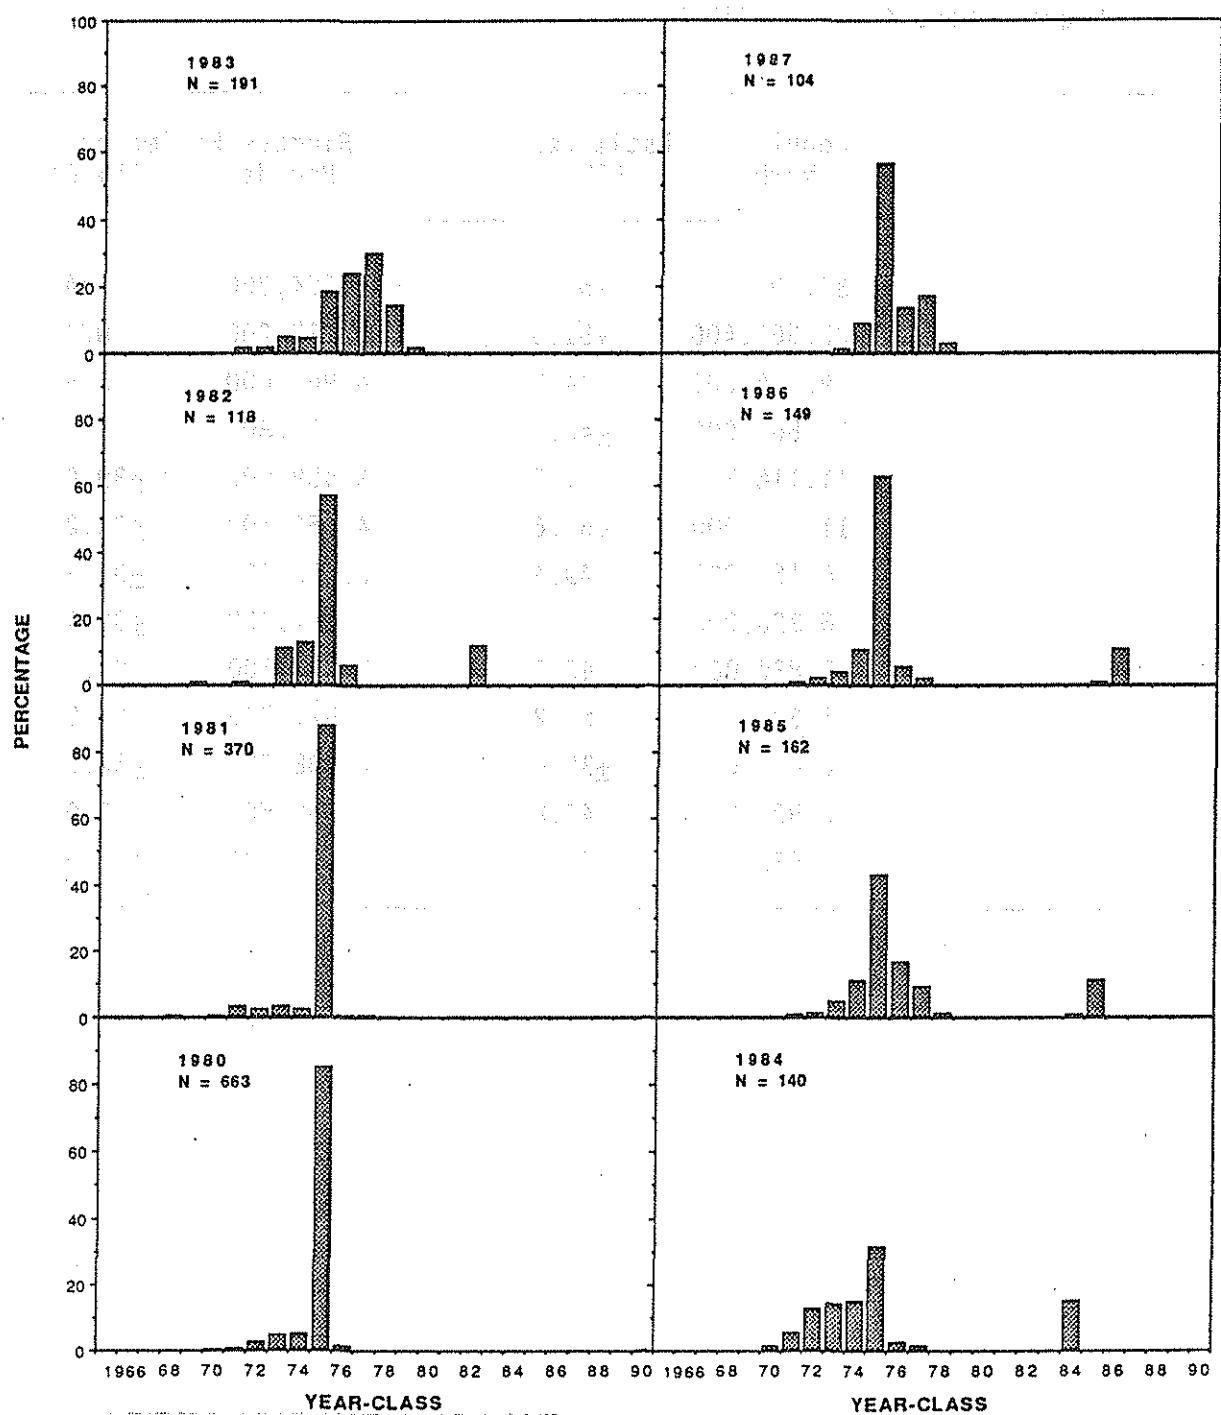

Figure 9. Age composition of subtidal gaper clams, Area 2, Yaquina Bay, 1980-87.

Table 39. Population and biomass estimates (95% CI) for gaper clams in Yaquina Bay, Area 2, 1975-87.

Year	Population Numbers	Estimates 95% CI	Biomass Pounds	Estimates 95% CI
1975	36,302,000	± 56.1	5,084,200	N/A
1976	25,566,400	± 51.5	5,217,200	N/A
1977	29,316,000	± 44.5	4,969,000	N/A
1978	10,560,000	± 48.9	4,136,800	N/A
1979	11,116,700	± 51.7	3,459,900	± 39.0
1980	11,050,000	± 51.6	4,252,500	± 33.2
1981	6,160,000	± 49.4	2,569,700	± 36.9
1982	6,320,000	± 42.6	4,424,900	± 30.4
1983	7,680,000	± 40.3	5,042,100	± 29.7
1984	5,600,000	± 59.2	3,528,700	± 54.2
1985	6,480,000	± 32.6	4,708,200	± 32.7
1986	5,920,000	± 48.8	4,350,600	± 50.0
1987	7,563,600	± 66.1	6,507,400	± 58.6
