SUMMARY

This annual report is in fulfillment of contract obligations with Bonneville Power Administration which is the funding source for the Oregon Department of Fish and Wildlife project "Annual Stock Assessment - Coded Wire Tag Program (ODFW)". Results for the 2004 contract period:

Objective 1 - In 2004 over 1 million juvenile salmon were coded-wire by this program (Table 1). This accounted for about 23% of the fish ODFW coded-wire tagged in 2004 for release in the Columbia Basin.

Objective 2 - In 2004 ODFW recovered and processed over 55,000 snouts collected from coded-wire tagged fish (Table 2). In addition, during 2004 we verified over 2,000 coded-wire tags recovered and returned to ODFW by other agencies.

Objective 3 - The survival data summarized below includes results for coded-wire groups funded by this program as well as coded-wire groups funded from other sources.

Fall Chinook

There are three stocks of hatchery fall chinook released by ODFW in the Columbia Basin; Tule, Upriver Bright, and Rogue River. The 10 year average survival of tule stock fall chinook was less than 0.15% for both programs (Table 3). Ocean recoveries were primarily in West Coast Vancouver Island and Washington coastal fisheries (Table 9). Freshwater recoveries were mainly at hatcheries, and secondarily in fisheries and on spawning grounds (Table 10).

The 10 year average survival of up-river bright stock fall chinook ranged from 0.09% for Umatilla Hatchery to 0.51% for Bonneville Hatchery fish released in the Umatilla River (Table 3). Survival of all three up-river bright programs has been low, but show improved survival for the 1998 brood (Table 3). Ocean catch of up-river bright fall chinook was mainly in Alaska through West Coast Vancouver Island fisheries (Table 9). Freshwater recoveries were mainly at hatcheries, with harvest accounting for less than ½ of the total number of freshwater recoveries (Table 10). Percent of harvest above Bonneville Dam was higher for fish released above Bonneville Dam (Table 10).

The 10 year average survival of Rogue River stock fall chinook was less than 1.0% for all three programs (Table 3). Survivals declined through the mid-1990's, but have improved somewhat in recent brood years (Table 3). These fish were caught primarily in Oregon, and secondarily in California and Washington ocean fisheries (Table 9). However, freshwater recoveries were very different for the three groups. Fish released in Big Creek were recovered mainly at the hatchery (Table 10). Fish released in Youngs Bay and Klaskanine River are recovered mainly in gillnet fisheries (Table 10).

Spring Chinook

A variety of stocks of spring chinook are released by ODFW hatcheries in the Columbia Basin. However, the programs can be grouped by release area; lower river terminal areas, Willamette Basin, and above Bonneville Dam. Willamette basin spring chinook stocks are released at four sites in the lower Columbia River to provide terminal fishery opportunities. The 10 year average survival of these groups ranged from 0.03% to 0.52% (Table 5). Ocean catch was mainly in Alaska through West Coast Vancouver Island fisheries (Table 9). Freshwater recoveries were mainly in lower river gillnet fisheries (Table 10).

The 10 year average survival of hatchery spring chinook released in the Willamette basin ranged from 0.39% for McKenzie Hatchery to 0.58% for

Willamette Hatchery (Table 4). Percent survival was generally below 0.5% during the 1990's, but has increased dramatically over the last 3 to 4 brood years to over 1.0% the 1998 brood year (Table 4). Ocean catch is mainly in Alaska, and secondarily in North Central British Columbia to Washington coastal fisheries (Table 9). Freshwater recoveries are predominately at the hatchery and in sport fisheries, with harvest accounting for 30% to 50% of the total freshwater recoveries (Table 10). Freshwater harvest of Molalla River releases is over 75% of the total freshwater recoveries (Table 10), due to the lack of a terminal recovery site in the Molalla River.

The 10 year average survival of hatchery spring chinook released above Bonneville Dam ranged from 0.13% for fish released in Lookingglass Creek to 0.54% for fish released in the Deschutes River (Table 6). Very few of these fish are recovered in ocean fisheries (Table 9). Freshwater recoveries were primarily at hatcheries (Table 10). However, for fish released in the Deschutes River 36% of the total freshwater recoveries were in sport and commercial fisheries (Table 10). Fish released in the Umatilla and Imnaha Rivers had substantial recoveries on spawning ground surveys (Table 10).

Steelhead

The 10 year average survival of hatchery steelhead ranged from 0.32% for winter steelhead released in the East Fork Hood River to 0.56% for summer steelhead released in Big Canyon Creek on the Wallowa River (Table 7). Ocean recoveries of ODFW Columbia Basin hatchery steelhead are rare (Table 9). The 14 ocean recoveries of steelhead tagcodes covered in this report were in Alaskan (1), British Columbian (10) and Oregon (3) fisheries. Freshwater recoveries were primarily at hatcheries and fish traps, and secondarily in sport fisheries and gillnet fisheries above Bonneville Dam (Table 10).

Coho

Releases of coho salmon from ODFW hatcheries in the Columbia basin can be divided into three groups by release location; above Bonneville Dam, at hatcheries below Bonneville Dam, and terminal areas in the Columbia Estuary. Average percent survival for the last 10 years ranged from 0.18% to 0.23% for releases above Bonneville Dam, from 0.89% to 2.13% for lower river hatchery releases, and from 0.93% to 1.76% for releases in terminal areas (Table 8).

Ocean recoveries of coho released in all three areas occurred primarily in Oregon and Washington Coastal fisheries, with smaller catches in West Coast Vancouver Island and California fisheries (Table 9). Although ocean recovery patterns are very similar, freshwater recovery patterns are very different for the three release areas. Coho released in estuary terminal areas are mainly recovered in lower river gillnet and sport fisheries, with very few hatchery recoveries (Table 10). Releases at hatcheries below Bonneville Dam are mostly recovered at hatcheries, but freshwater harvest accounts for 19% to 30% of the total freshwater recoveries (Table 10). Freshwater harvest of coho released above Bonneville Dam is lower than that of coho released below the dam, but the coho released above Bonneville Dam contribute to gillnet fisheries above the dam (Table 10). Coho released above Bonneville Dam also have fewer recoveries at hatcheries and fish traps than coho released at lower river hatcheries. However, this may be at least partly a reflection of differences in sampling locations and techniques rather than differences in survival.

INTRODUCTION

In September 1989 the Oregon Department of Fish and Wildlife received a contract from the Bonneville Power Administration to begin a project of

annually coded-wire tagging production groups of anadromous salmonids not currently tagged. Some groups of hatchery production fish were already being tagged by other programs. The Bonneville Power Administration contract consisted of coded-wire tagging the remaining untagged production groups for the future data base. This project began in 1990 to coded-wire tag groups of juvenile anadromous salmon produced at Oregon hatcheries. During 2004 this contract funded approximately 23% of ODFW's Columbia Basin coded-wire tagging.

Tagging will enable evaluation of survival and contribution rates. As the fish mature and are captured in various fisheries or return to release / recapture facilities, they are sampled to recover coded-wire tags. All recoveries of coded-wire tagged fish are reported to the Pacific States Marine Fisheries Commission (PSMFC). Release and recovery information is stored along with sampling and mark/unmarked release ratios. This information is then used to estimate survival rates and catch contribution rates for each production lot of fish reared and released at each hatchery. This data is used to evaluate effectiveness of each hatchery as well as various rearing and release practices. Evaluation of the various hatchery and natural production projects will be needed to measure the effectiveness of any mitigation program and to help direct future efforts in maintaining or enhancing fish runs in the Columbia Basin. This information is also used by salmon harvest managers in developing scenarios that will allow harvest of excess hatchery fish while protecting threatened and endangered natural stocks.

The vision of the Fish and Wildlife Plan (NPPC 2000) is of a Columbia River ecosystem "...that sustains an abundant, productive, and diverse community of fish and wildlife, mitigating across the basin for adverse effects to fish and wildlife caused by the development and operation of the hydro system and providing the benefits from fish and wildlife valued by the people of the region." The Fish and Wildlife Plan is primarily a habitat-based program that focuses on protecting and rebuilding healthy, naturally producing fish and wildlife populations in the Columbia River basin. Although focused on natural production the Fish and Wildlife Plan acknowledges a role for artificial production of fish "...to replace capacity, bolster productivity, and alleviate harvest pressure on weak, naturally spawning resident and anadromous fish populations." The coded-wire tag program is a critical component of the post-release monitoring of artificial production programs. The coded-wire tag project provides data that can be used to assist in addressing some of the basin wide artificial production strategies identified by the Fish and Wildlife Plan, including: using an experimental, adaptive management design; aggressively evaluate risks and benefits; monitor impacts to wild populations (straying and mixed stock fisheries); and reporting on results in relation to the artificial production programs objectives. The coded-wire tag project also assists in the monitoring of in river and ocean fisheries to "...routinely estimate stock composition and age specific abundance, escapement, catch, and age distribution." (NPPC 2000, Basin wide Strategies D. 5. Harvest Monitoring), and can assist in providing information for subbasin assessments, such as "...mainstem survival rates, ocean and in river harvest rates, effects of interactions with fish from other subbasins, and ocean conditions." (NPPC 2000, Subbasins A. 3. Subbasin Assessment)

METHODS AND MATERIALS

The adipose fin clip + coded-wire tag (Jefferts et.al. 1963) was chose as the method of marking because its use is well established in the region, there is a region wide sampling program for this mark, and there is an established regional data reporting, storing, and access system. In 1989 a committee of agency and tribal scientists recommended the number of fish tagged per group for this project be based on producing a minimum of 30 actual tag recoveries per group. Based on historic levels of survival, harvest, and sampling, the

following levels of tagging should meet that goal; tag 25,000 for groups with expected survivals of 0.5% or higher, and tag 50,000 for groups with expected survivals of 0.5% or lower. Some groups of 30,000 are used for Willamette Basin spring chinook to maintain equal sample size with ongoing ODFW research projects funding other tagging at those hatcheries. These levels generally agree with Reisenbichler and Hartmann (1978) who recommended tagging 25,000 fish per group for estimation of fish contribution. However, the increasing complexity of fisheries management regimes requires much higher levels of tagging (Hankin and Mohr 1990).

Objective 1. Insure all ODFW Columbia Basin hatchery coho and chinook production releases have a representative CWT group included in the release. Specific tasks and methods follow:

- a) Determine groups to tag and number of fish to tag. This is a three step process. First, all production releases are identified, based on program intent (ongoing regular smolt production), number of fish released (50,000 or more), and fish of an acceptable size (at least 2.0 gm/fish). Second, groups with adequate tagging funded by other sources are eliminated from the list. Finally, the number of fish to tag is determined based on the expected survival, generally 25,000 to 50,000 per group.
- b) The identified groups of fish are tagged based on the manufactures recommendations and standard techniques for coded-wire tagging (Jenkinson and Bilton 1981).
- c) Pre-release checks of 500 fish per group (PSC 1995) are made at least 4 weeks after tagging (Blankenship 1981).
- d) All release information is reported to the Pacific States Marine Fisheries Commission and is available on their on-line computer database.

Objective 2. Recover coded-wire tags from snouts of fish tagged under Objective 1. Specific tasks and methods follow:

- a) Snouts collected from marked fish sampled in fisheries, hatcheries, and other recovery areas are frozen and transported to the ODFW Fish Identification head lab in Clackamas, Oregon.
- b) Tags are recovered, read and stored using standard techniques. ODFW tags recovered by other agencies are sent to the Clackams lab for verification.
- c) All recovery information is reported to the Pacific States Marine Fisheries Commission and is available on their on-line computer database.

Objective 3. Prepare annual report. Specific tasks and methods follow:

- a) Compile release and recovery information from all CWT groups released in the Columbia Basin by ODFW.
- b) Calculate total percent survival $[(\text{total estimated recoveries}/\text{number of tagged fish released}) \times 100]$ and percent survival by area $[(\text{total estimated recoveries in each area}/\text{number of tagged fish released}) \times 100]$ for each CWT group. Calculate 10 year averages of the above information by hatchery program (species/stock/release location).
- c) Compile and submit report to BPA by 90 days after end of contract. Report published by BPA.

RESULTS

Objective 1. We completed coded-wire tagging and ad-clipping (Ad+CWT) a total of over 1.0 million juvenile 2003 brood spring chinook, fall chinook, and coho salmon (Table 1). The total represents 25 different tag groups. Operational costs for this tagging totaled about \$119,000 (without administrative overhead), or an average of \$113 per thousand fish tagged, ranging from \$91/1,000 to \$132/1,000.

Table 1. Fish tagged and respective estimated operational costs. (January 1, 2004 to December 31, 2004).

Objective 2. During 2004 we processed a total of 55,556 tags at the Clackamas laboratory. These consisted of fish from sport, commercial, tribal, hatchery, spawning ground surveys, and miscellaneous other fisheries (Table 2). During 2004 we verified 2,124 ODFW coded-wire tags recovered and returned to ODFW by other agencies.

Objective 3. A summary of available coded-wire tag release and recovery information for each group of Ad+CWT tagged fish released from Oregon Department of Fish and Wildlife hatcheries in the Columbia Basin is presented in Appendix A. This includes Ad+CWT tagged fish funded by this contract as well as Ad+CWT tagged fish funded from other sources. Data in Appendix A covers the last 10 brood years with complete recovery data. Recovery data is available through the 2003 return year. This equates to complete recovery

data for the 1989 - 1998 brood years for chinook salmon, 1990 - 1999 brood years for steelhead, and 1991 - 2000 brood years for coho salmon.

DISCUSSION

The following discussion section consists of two parts: 1) Tables of percent survival data for all programs (total survival, survival to ocean fishery areas, and survival to freshwater recovery areas); 2) Discussions of results for each individual ODFW Columbia Basin hatchery.

The following estimates of percent survival are based on releases of Ad+CWT marked hatchery juveniles and their subsequent recovery as adults, in ocean and freshwater fisheries, at hatcheries or fish traps, and on spawning grounds. This includes Ad+CWT tagged fish funded by this contract and fish funded from other sources. Percent survival is calculated as (total estimated recoveries/number of tagged fish released)*100. The estimated brood year percent survival is the percent survival of the Ad+CWT group representing that brood year. When more than one Ad+CWT group is available for a brood year the brood year percent survival is calculated as the weighted average of the Ad+CWT groups. Percent survival estimates are weighted by the total number of fish, both marked and unmarked, associated with each Ad+CWT group.

In using the recovery data in this report several cautions need to be kept in mind. (1) The estimated survivals are minimum survivals. Some CWT fish are caught or escape to areas that are not sampled, or are not sampled in a way that allows for estimation of the total number of CWT fish in that area. (2) Spawning ground recoveries of Ad+CWT fish are generally not expanded. Only the number of observed recoveries is available. (3) Most freshwater fisheries outside of the Columbia River system are not sampled. (4) The reduced salmon fishing seasons of the recent years have the potential to bias survival estimates. Reduced harvest should result in increased escapement. However, not all escapement areas are sampled, or sampled equally. Some hatchery traps include a barrier across the stream while others rely on fish swimming in without any barrier. Also, some groups of fish are/were released in off-site areas without adult recapture facilities (i.e. coho salmon reared at Big Creek Hatchery and released in the Tualatin River).

In the late 1990's marine survival of hatchery salmon increased dramatically. This increased survival resulted in large increases in the numbers of returning adult hatchery salmon and steelhead, and thus increased numbers of CWT recoveries at hatcheries. The increased returns began with the 2000 adult return year, and we started processing the increased number of CWT recoveries in 2001. Over the last 4 years (2001 through 2004) we have averaged about 48,000 CWT recoveries processed per year. This is double the average workload from the prior 9 years (1992 through 2000), average of about 24,000 CWT recoveries processed per year. Although we have doubled the number of CWT recoveries processed each year we have not been able to keep up with the rate at which they are being collected. This has resulted in a backlog of

unprocessed CWT recoveries from hatcheries. Currently most, but not all, of the backlog have been processed. However, there is also a backlog in the data entry, validation and upload process. The result is that while we have ocean and freshwater recoveries through 2003, some hatchery return information is incomplete. This has some effect on estimated percent survival of steelhead and chinook CWT groups. However, these species return over multiple years, and for logistical and timing reasons their hatchery CWT recoveries are generally processed before coho hatchery CWT recoveries. Survival of Big Creek and Sandy hatchery 1998 brood coho is missing hatchery adult returns (Table 8), and will increase as we clear the backlog of CWT recoveries.

Table 6. Estimated 1989 through 1998 brood year percent survival for ODFW spring chinook programs in the Columbia Basin above Bonneville Dam. Programs are identified by hatchery, stock, and release site.

^a = Does not include data from all ten years.

Big Creek Hatchery

Big Creek Hatchery is located 2 miles south of Knappa off Highway 30 near the mouth of the Columbia River. The hatchery, originally built in 1939-41, rears and releases tule and Rogue fall chinook, coho salmon, and winter steelhead. The winter steelhead have not been marked with coded-wire tags for evaluation.

Tule stock fall chinook 1989 to 1998 broods percent survival averaged 0.14%, and ranged from 0.03% to 0.28% (Table 3). Survival has been consistently low over the last 10 brood years (Figure 2). Ocean catch was primarily in West Coast Vancouver Island and Washington Coastal fisheries (Table 9). Freshwater recoveries were mainly at hatcheries, with freshwater sport and lower river gillnet catch each composing 10% of the total freshwater recoveries (Table 10).

Experimental releases of Rogue River stock fall chinook at Big Creek began in 1983. Good survival and contribution rates to Oregon fisheries resulted in expansion of the program. Rogue River stock fall chinook, 1989 to 1995 broods, percent survival averaged 0.68%, and ranged from 0.18% to 1.56% (Table 3). Survival has generally declined over the last 10 brood years (Figure 2). Ocean catch was mainly in Oregon fisheries, with smaller contributions to California and Washington Coast fisheries (Table 9). Freshwater recoveries were mainly at hatcheries, with freshwater sport and lower river gillnet catch composing 19% of the total freshwater recoveries (Table 10). Beginning with the 1995 brood the release site was switched to Klaskanine Hatchery, to reduce straying.

The 1991 to 2000 brood Big Creek stock coho released in Big Creek survived at an average rate of 1.30%, and ranged from 0.52% to 3.17% (Table 8). Coho survival was generally low for the 1991 to 1996 broods, but has increased since the 1996 brood (Figure 2). Ocean catch was mainly in Oregon and Washington coastal fisheries (Table 9). Freshwater recoveries were 69% hatchery returns and 30% sport and lower river gillnet catch (Table 10). The same coho stock released in the Tualatin River survived at an average rate of 0.04% for the 1991 to 1996 broods. Releases in the Tualatin River were discontinued after the 1996 brood.

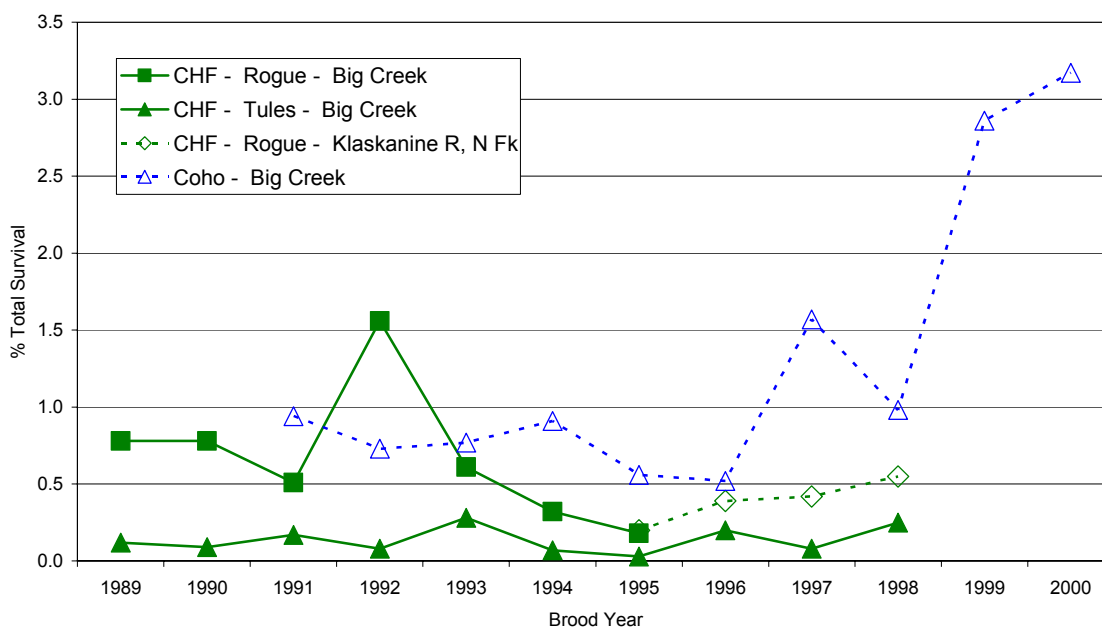

Figure 2. Percent survival by brood year for Big Creek Hatchery programs.

Klaskanine Hatchery

Klaskanine Hatchery is located 21 miles southeast of Astoria, Oregon on Highway 202 adjacent to the Klaskanine River. The hatchery, originally built in 1913, was expanded and remodeled in 1953. Budget cuts have reduced hatchery staffing to 1 person and eliminated all rearing programs. Historically, the hatchery reared tule fall chinook, coho and winter steelhead. Presently, the hatchery serves as an acclimation and adult recapture facility for Rogue stock fall chinook and Big Creek stock winter steelhead. The winter steelhead have not been marked with coded-wire tags for evaluation.

Rogue Stock fall chinook releases began with the 1995 brood. Average survival for the 1995 to 1998 brood years was 0.39%, which is comparable to the same stock released in other lower Columbia River areas (Table 3). Ocean catch was primarily in Oregon fisheries, with smaller contributions to California and Washington Coastal fisheries (Table 9). Freshwater recoveries were primarily in lower river gillnet fisheries (Table 10).

The tule fall chinook program was discontinued after the 1988 brood year, and the coho program was discontinued after the 1994 brood year. Release and recovery data for Klaskanine Hatchery 1991 to 1994 brood coho is reported in Appendix A.

Clatsop Economic Development Commission (CEDC)

CEDC operates freshwater ponds and estuary net pens in Youngs Bay and adjacent areas near Astoria, Oregon. Their programs include releases of coho, fall chinook, and spring chinook salmon in cooperation with ODFW hatcheries.

Tule fall chinook production was discontinued after the 1987 brood year. Experimental releases of Rogue stock fall chinook in Blind Slough and Tongue Point were begun with the 1995 brood year. Upriver Bright stock fall chinook were released in Youngs Bay (1994 & 1997 broods) and at Tongue Point (1995 & 1996 broods). Release and recovery data for CWT groups associated with these programs is reported in Appendix A.

Rogue River stock fall chinook released in Youngs Bay/South Fork Klaskanine River (1989 to 1998 broods) survived at an average rate of 0.48% and ranged from 0.08% to 1.37% (Table 3). Survival has generally declined over the last 10 brood years (Figure 3). Ocean catch was primarily in Oregon fisheries, with smaller contributions to California and Washington Coastal fisheries (Table 9). Freshwater recoveries were primarily in lower river gillnet fisheries (Table 10).

Release of Willamette Basin spring chinook by CEDC began with the 1988 brood. A variety of different Willamette Basin stocks have been used over the years. The original releases were in Youngs Bay and South Fork Klaskanine River. The program was expanded to Blind Slough and Tongue Point beginning with the 1994 brood year. Releases in South Fork Klaskanine River were discontinued after the 1995 brood year. Spring chinook released in terminal areas (1989 to 1998 broods) had similar average survivals; Blind Slough 0.39%, Tongue Point 0.52%, and Youngs Bay 0.48% (Table 4). Generally, survival of spring chinook released in the estuary terminal areas was below 0.5% (Figure 3) and less than the survival of spring chinook released at the Willamette Basin hatcheries, until the 1996 brood (Table 4). The very few spring chinook released by CEDC that are recovered in the ocean are caught primarily in Alaskan ocean fisheries (Table 9). Freshwater recoveries are primarily in lower river gillnet fisheries, with a small number recovered at hatcheries and in freshwater fisheries (Table 10).

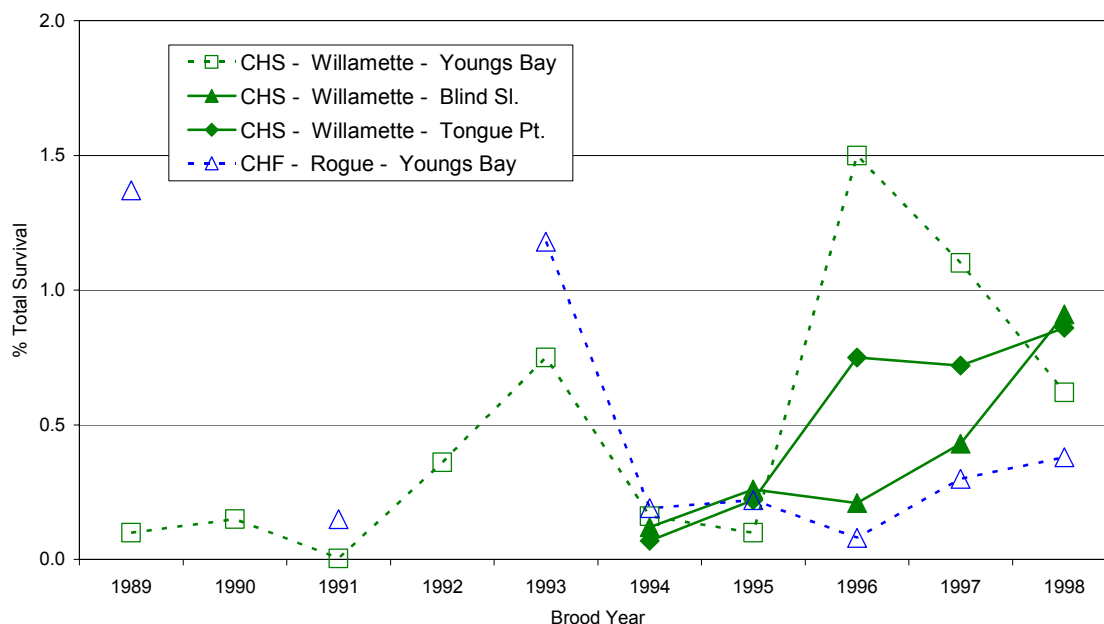

Figure 3. Percent survival by brood year for CEDC chinook programs.

Releases of coho salmon in Columbia Estuary terminal areas use a variety of stocks and release locations (Appendix A). Using data for five of the longer-term CEDC coho stock/release site data sets (brood years 1991 through 2000) 10 year average survival ranged from 0.93% to 1.76% (Table 8). Survival has been variable over the last 10 brood years (Figure 4). Survival of coho released by CEDC is generally higher than that seen for the same stocks released from ODFW lower Columbia hatcheries (Table 8). Ocean catch of CEDC coho is very similar to that of coho salmon from ODFW lower Columbia hatcheries, mainly in Oregon and Washington coastal fisheries (Table 9). Percent survival to freshwater sport fisheries is very similar for CEDC and other ODFW Columbia Basin coho programs (Table 10). However, coho released by CEDC have much higher recoveries in gillnet fisheries and much lower recoveries at hatcheries than the same stocks released from ODFW Columbia Basin hatcheries (Table 10).

Gnat Creek Hatchery

Gnat Creek Hatchery is located east of Knappa off Highway 30 on Gnat Creek a tributary to the Lower Columbia River. Gnat Creek Hatchery released summer and winter steelhead and cutthroat trout, none of which were coded-wire tagged for evaluation. Due to budget cuts the hatchery was switched in 1996 to rearing Willamette Basin stock spring chinook for acclimation and release in lower Columbia River net pens in cooperation with CEDC. For discussion of these programs see the CEDC section above.

Eagle Creek National Fish Hatchery

Eagle Creek National Fish Hatchery (NFH) is located on Eagle Creek a tributary of the Clackamas River southeast of Portland. Eagle Creek NFH presently rears and releases coho salmon in Eagle Creek. Additional coho are reared for ODFW, and are transported to the CEDC net pens for acclimation in Youngs Bay near Astoria. For results of the Youngs Bay releases see the CEDC section above.

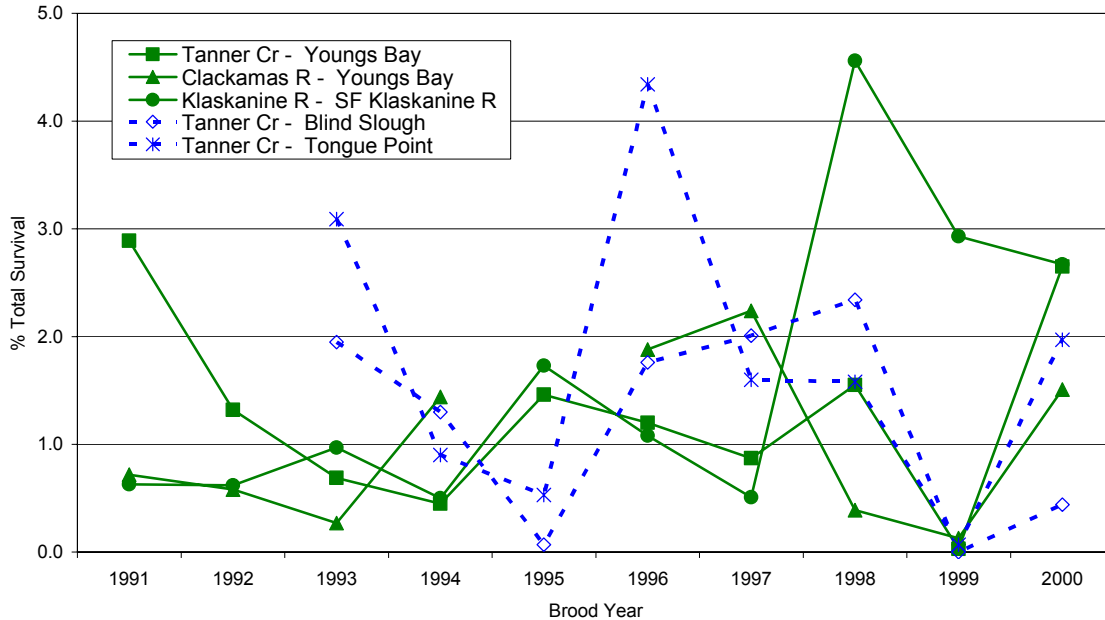

Figure 4. Percent survival by brood year for CEDC coho programs.

Clackamas Hatchery

Clackamas Hatchery is located on the Clackamas River 4 miles west of Estacada near McIver Park. Clackamas Hatchery rears and releases spring chinook salmon, summer and winter steelhead. Due to water quality and quantity limits, eggs collected at Clackamas Hatchery are sent to other hatcheries for incubation and early rearing. Steelhead eggs go to Irrigon and Oak Springs hatcheries. Spring chinook eggs go to Willamette and Oxbow for incubation and then to Marion forks for rearing. Juveniles are then returned to Clackamas for final rearing and release. None of the Clackamas Hatchery summer and winter steelhead releases have been marked with coded-wire tags for evaluation.

The 1989 to 1998 brood Clackamas River stock spring chinook released in the Clackamas River survived at an average rate of 0.58% and ranged from 0.22% to 1.94% (Table 4). The same stock released in the Sandy River (1991 to 1998 broods) survived at an average rate of 0.27% and ranged from 0.05% to 0.96% (Table 4). For the 1989 to 1997 brood years Clackamas Hatchery spring chinook survival was fairly consistent at about 0.5% (Figure 5). However, survival jumped to almost 2.0% in 1998 (Figure 5), the highest for any 1998 brood Willamette Basin spring chinook program. The same stock of hatchery spring chinook released in the Sandy River showed a similar pattern in survival but the absolute values were lower (Figure 5). This is most likely the result of much lower levels of sampling for CWT spring chinook in the Sandy Basin.

Ocean recoveries of the two groups were fairly similar, predominately in Alaskan and Canadian (West Coast Vancouver Island and North Central British Columbia) fisheries (Table 9). Freshwater recoveries are mainly at hatcheries and fish traps, with freshwater sport and lower river gillnet fisheries accounting for 37% to 78% of the total freshwater recoveries for the Clackamas River and Sandy River release groups, respectively (Table 10).

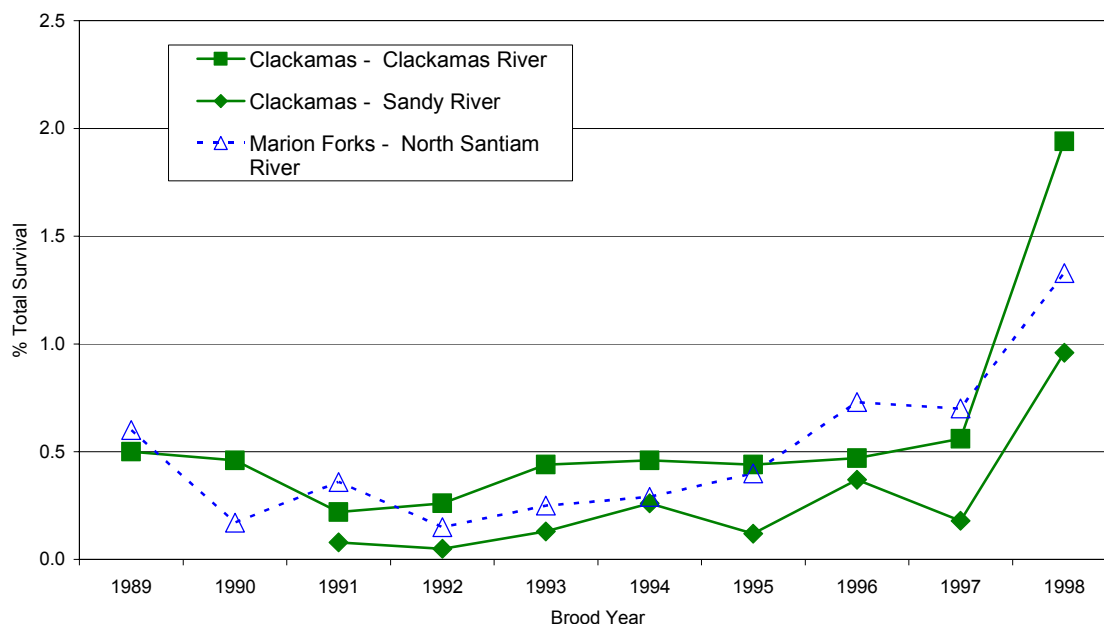

Figure 5. Percent survival by brood year for Clackamas and Marion Forks Hatchery spring chinook programs.

Marion Forks Hatchery

Marion Forks Hatchery is located on the North Santiam River 10 miles east of Idana on Highway 22. Marion Forks Hatchery rears and releases spring chinook salmon, winter steelhead, rainbow and cutthroat trout. Although prior brood years of winter steelhead have been coded-wire tagged, none were tagged for the current 10 brood years. All other rainbow and cutthroat trout released by the Marion Forks Hatchery were not coded-wire tagged for evaluation.

The 1989 to 1998 brood years of Marion Forks spring chinook survived at an average rate of 0.50% and ranged from 0.15% to 1.33% (Table 4). Survival for Marion Forks Hatchery spring chinook declined from the 1989 to 1990 brood years and has stayed below 0.4% until the 1995 brood year (Figure 5). There is an increasing trend in survival since the 10 year survival low of 0.15% for the 1992 brood (Figure 5). Survival increased dramatically for the 1998 brood year, to 1.33% (Table 4). This was the second highest survival for the 1998 brood year Willamette Basin hatchery spring chinook programs.

Ocean recoveries of these spring chinook are mainly in Alaska and British Columbia fisheries (Table 9). Marion Forks spring chinook had the second highest average percent survival to freshwater fisheries, but the lowest average percent survival to hatchery returns of any Willamette Basin hatchery spring chinook program (Table 10). Freshwater catch averaged 51% of the freshwater recoveries for Marion Forks Hatchery spring chinook. This is much higher than most other Willamette Basin hatchery spring chinook programs (Table 10). This difference is most likely related to adult collection methods at the hatcheries. Marion Forks Hatchery only collects adult spring chinook in the fall. The other Willamette Basin spring chinook hatcheries initially open their adult traps in the summer, close them in late summer and then re-open the traps in the fall, just prior to spawning.

South Santiam Hatchery

South Santiam Hatchery is located below Foster Dam on the South Santiam River near Sweet Home. South Santiam Hatchery rears and releases spring chinook salmon and summer steelhead. Summer steelhead released by South Santiam Hatchery have not been coded-wire tagged to permit evaluation.

The 1989 to 1998 brood South Santiam spring chinook survived at an average rate of 0.50% and ranged from 0.18% to 1.17% (Table 4). Survival declined from the 1989 to 1992 brood years, but has shown an increasing trend since the 1992 brood reaching 1.17% for the 1998 brood year (Figure 6).

Ocean recoveries of these spring chinook are almost exclusively in Alaskan and Canadian fisheries (Table 9). South Santiam Hatchery spring chinook freshwater recoveries are mainly hatchery returns (Table 10). Freshwater catch (sport and lower river gillnet combined) composed 51% of the average freshwater recoveries for South Santiam Hatchery spring chinook.

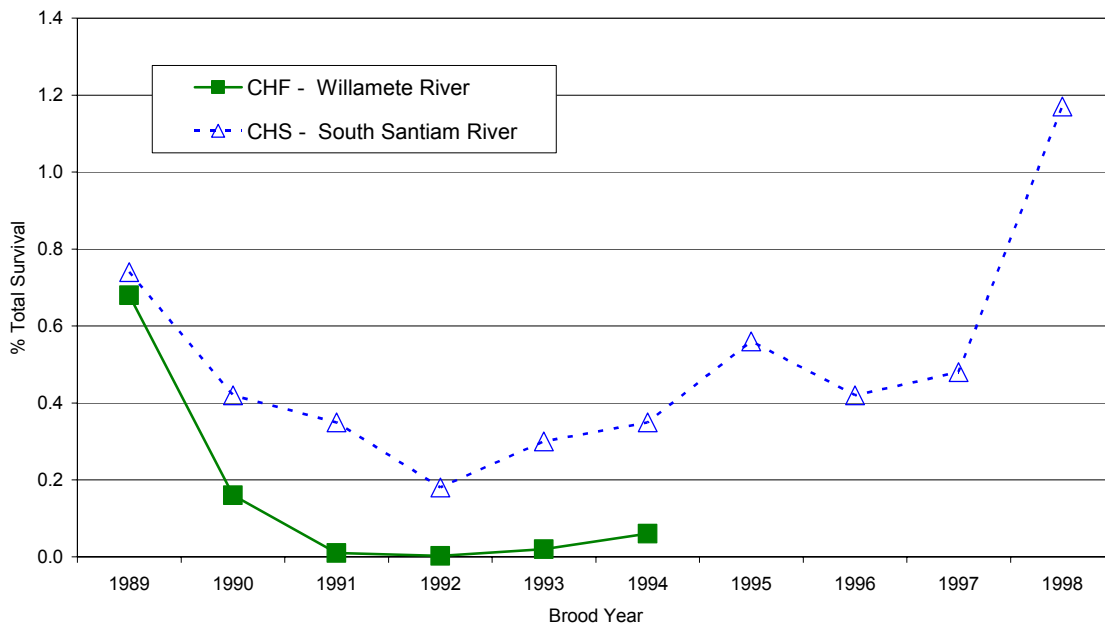

Figure 6. Percent survival by brood year for South Santiam Hatchery programs.

Stayton Rearing Pond

Stayton Pond, a refurbished gravel pit located south of Stayton, was operated as a satellite of the South Santiam Hatchery. Stayton Pond reared tule stock fall chinook, but production was discontinued after the 1994 brood year due to budget cuts and flood damage to the facility.

The 1989 to 1994 brood Stayton Pond fall chinook survived at an average rate of 0.16%, ranging from 0.00% to 0.68% (Appendix A). Survival was consistently below 0.2% except for the 1989 brood year (Figure 6). Ocean recoveries were mostly in West Coast Vancouver Island and Washington Coastal fisheries, hatchery returns comprised 87% and freshwater sport 13% of freshwater recoveries (Appendix A).

Roaring River Hatchery

Roaring River Hatchery is located 11 miles southeast of Scio off State Highway 226. The hatchery rears and releases winter steelhead and rainbow trout. None of these fish have been coded-wire tagged for evaluation.

McKenzie Hatchery

McKenzie Hatchery is located on the McKenzie River 16 miles east of Springfield. The hatchery rears and releases spring chinook salmon and summer steelhead. None of the summer steelhead released from McKenzie Hatchery have been coded-wire tagged for evaluation.

The 1989 to 1998 brood McKenzie Hatchery spring chinook survived at an average rate of 0.39% and ranged from 0.11% to 1.14% (Table 4). Survival was low from the 1989 through 1995 brood years, but has increased since then, reaching over 1.0% for the 1998 brood (Figure 7).

Ocean recoveries of these spring chinook are almost exclusively in Alaskan and West Coast Vancouver Island fisheries (Table 9). McKenzie Hatchery spring chinook freshwater recoveries are mainly hatchery returns (Table 10). Freshwater catch (sport and lower river gillnet combined) composed 29% of the average freshwater recoveries for McKenzie Hatchery spring chinook.

McKenzie Hatchery was involved in a net pen acclimation experiment for spring chinook. The goal of the experiment was to determine the effect of both acclimated and direct smolt releases at several sites below Willamette Falls, on catch in the Lower Willamette fishery. The experiment involved releases for the 1994 to 1999 brood years, although some fish were also released below Willamette falls for the 1992 and 1993 broods. Results by tagcode are reported in Appendix A. For a discussion of the experiment see Schroeder et.al. (2001).

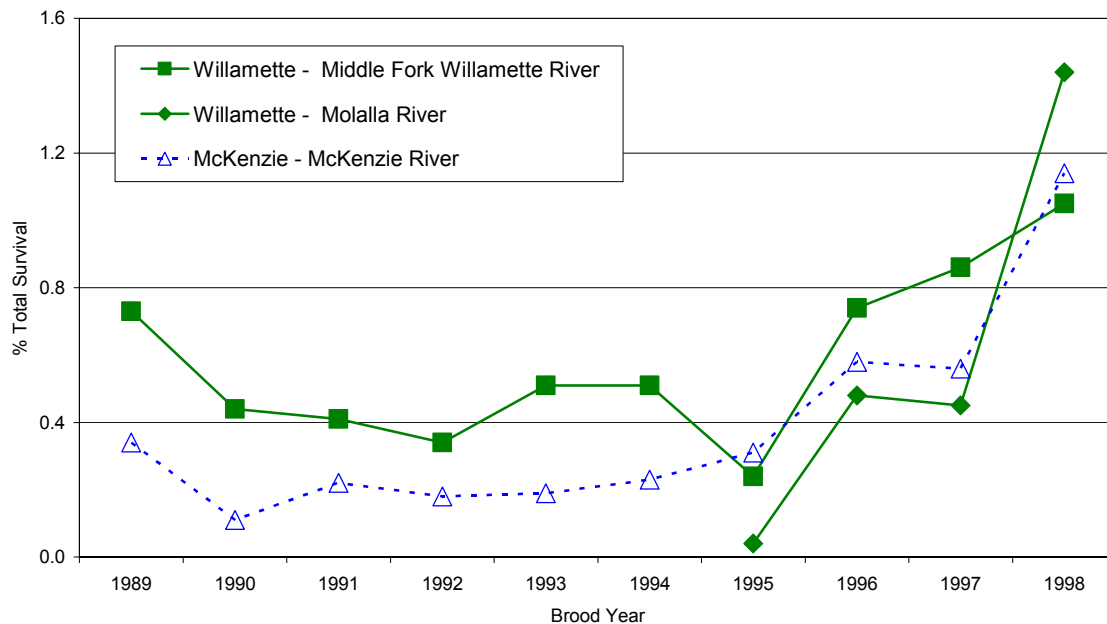

Figure 7. Percent survival by brood for Willamette & McKenzie hatchery spring chinook programs.

Leaburg Hatchery

Leaburg Hatchery is located on the McKenzie River off Highway 126, 18 miles east of Springfield. Leaburg Hatchery rears and releases summer steelhead and rainbow trout. None of these fish have been coded-wire tagged for evaluation.

Willamette Hatchery

Willamette Hatchery is located on the Middle Fork Willamette River 1 mile east of Oakridge off Highway 58. Willamette Hatchery rears and releases spring chinook salmon, summer and winter steelhead and rainbow trout. None of the steelhead or rainbow trout have been coded-wire tagged for evaluation.

The 1989 to 1998 brood Willamette Hatchery spring chinook survived at an average rate of 0.58% and ranged from 0.24% to 1.05% (Table 4). During this time period this was the second highest average survival any Willamette Basin spring chinook program. Survival declined from 1989 to 1995 broods, but has increased since the 1996 brood year (Figure 7). Willamette Hatchery releases South Santiam stock spring chinook in the Molalla River. These fish averaged 0.60% survival for the 1995 to 1998 broods (Table 4). This was the highest average survival in Table 4, but doesn't include the poor survival brood years from 1989 through 1994.

Ocean recoveries of spring chinook released from Willamette Hatchery are mainly in Alaska and British Columbia fisheries (Table 9). Willamette Hatchery spring chinook freshwater recoveries are mainly hatchery returns with freshwater catch composing 33% of the average total freshwater recoveries (Table 10). Catch composed 77% of all freshwater recoveries of Molalla River releases, due to the lack of a terminal recovery location in the Molalla River (Table 10).

Sandy Hatchery

Sandy Hatchery is located on the Sandy River 1 mile northeast of the city of Sandy off Highway 26. Sandy Hatchery rears and releases coho salmon, rainbow and brook trout. Starting with the 1999 brood year Sandy Hatchery began acclimating and releasing a portion of the spring chinook reared at Clackamas Hatchery and released in the Sandy Basin. None of the rainbow or brook trout released by Sandy Hatchery were coded-wire tagged for evaluation.

The 1991 to 2000 brood years of Sandy River stock coho released in the Sandy River survived at an average rate of 0.89%, and ranged from 0.32% to 1.93% (Table 8). Coho survival was generally low for the 1991 to 1996 broods, but has increased since then (Figure 8). Ocean catch was mainly in Oregon and Washington coastal fisheries (Table 9). Sandy Hatchery coho freshwater recoveries are mainly hatchery returns (Table 10). Freshwater sport and lower river gillnet catch composed 28% of the average freshwater recoveries for Sandy Hatchery coho.

Cascade Hatchery

Cascade Hatchery is located off Highway 84 just above Bonneville Dam. Cascade Hatchery rears coho salmon that are acclimated and released in the Umatilla River and in upper Columbia River tributaries.

The 1991 to 2000 brood years of Tanner Creek stock coho released in the Umatilla River survived at an average rate of 0.23%, and ranged from 0.01% to 0.42% (Table 8). The 1991 to 1997 brood years released in the Yakima River survived at an average rate of 0.18%, and ranged from 0.05% to 0.48% (Table 8). Starting with

the 1998 brood year the Yakima River releases were switched to releases in the Methow and Wenatchee Rivers. Survival for 1998 to 2000 brood coho released from these two sites is reported in Appendix A. Survival for these above Bonneville Dam coho programs has been relatively low since the 1991 brood year (Figure 8), and is generally lower than the survival of the same stock released below Bonneville Dam (Table 8). These programs have not shown the recent large increases in survival seen for coho released below Bonneville Dam (Table 8).

Ocean catch of Tanner Creek stock coho released in the Umatilla and Yakima Rivers was mainly in Oregon and Washington coastal fisheries (Table 9). Freshwater recoveries of these coho were mainly fisheries (Yakima) and hatcheries (Umatilla) (Table 10). Unlike coho released below Bonneville Dam, the coho released above the dam contributed to gillnet fisheries above the dam, about 50% of the total gillnet catch (Table 10). Percent survival to hatchery recovery for Tanner Creek stock coho released in the Umatilla and Yakima Rivers was lower than that for the same stock released below the dam (Table 10). This may be related to the sampling programs for CWT coho in the Umatilla and Yakima basin escapement.

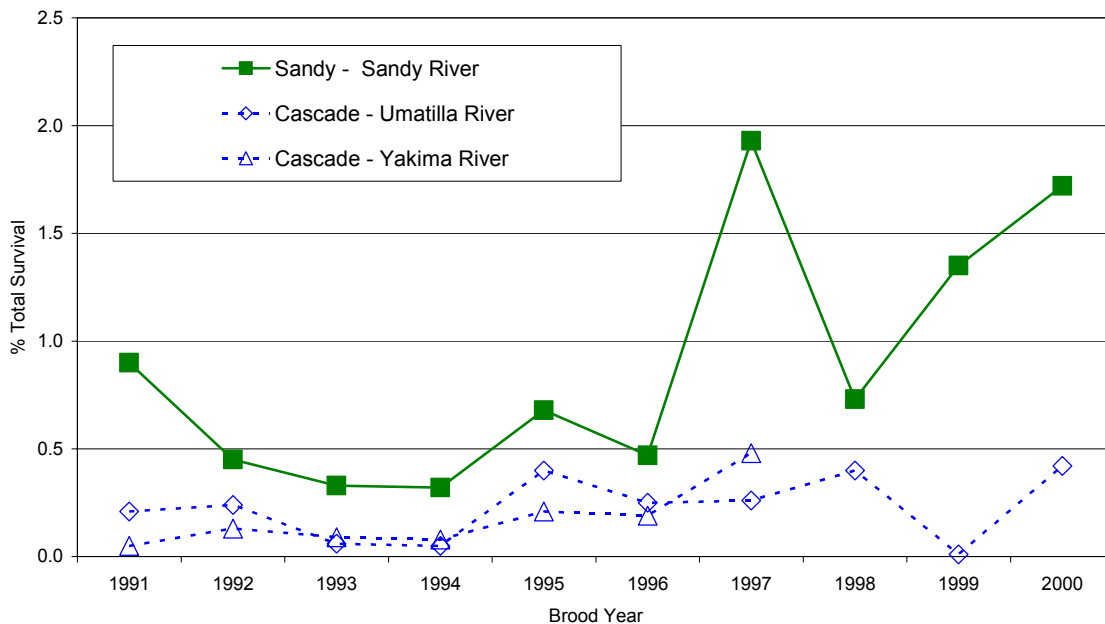

Figure 8. Percent survival by brood for Sandy & Cascade Hatchery coho programs.

Bonneville Hatchery

Bonneville Hatchery is located adjacent to the Columbia River, off Highway 84 just below Bonneville Dam. Bonneville Hatchery rears and releases up-river bright fall chinook, sockeye and coho salmon. Bonneville Hatchery reared and released spring chinook salmon smolts until the 1992 brood year for Umatilla River releases, and the 1993 brood for West Fork Hood River releases. In addition, tule stock fall chinook production was discontinued after the 1995 brood year. Appendix A reports CWT release and recovery data for these programs.

Bonneville Hatchery releases up-river bright stock fall chinook in Tanner Creek and in the Umatilla River. Average percent survival for the 1989 to 1998 broods, released in Tanner Creek was 0.29%, and for fish released in Umatilla River was 0.51% (Table 3). Survival has generally been low for both groups over this time

period, except for a dramatically increased survival for the 1998 brood year (Figure 9). Ocean catch for both groups was mainly in Alaskan and Canadian (West Coast Vancouver Island and North Central British Columbia) fisheries (Table 9). Freshwater recoveries were mainly hatchery returns for both groups, with freshwater catch (sport and gillnet combined) accounting for 30% to 40% of the total average freshwater recoveries (Table 10).

The 1991 to 2000 brood years of Bonneville Hatchery coho survived at an average rate of 2.13%, and ranged from 0.42% to 5.91% (Table 8). Survival of Bonneville Hatchery coho generally declined from the 1991 to 1996 brood years, but has increased substantially since then (Figure 9). Ocean catch was mainly in Oregon and Washington coastal fisheries (Table 9). Bonneville Hatchery coho freshwater recoveries are mainly hatchery returns, with freshwater sport and lower river gillnet catch comprising 18% of the average freshwater recoveries (Table 10).

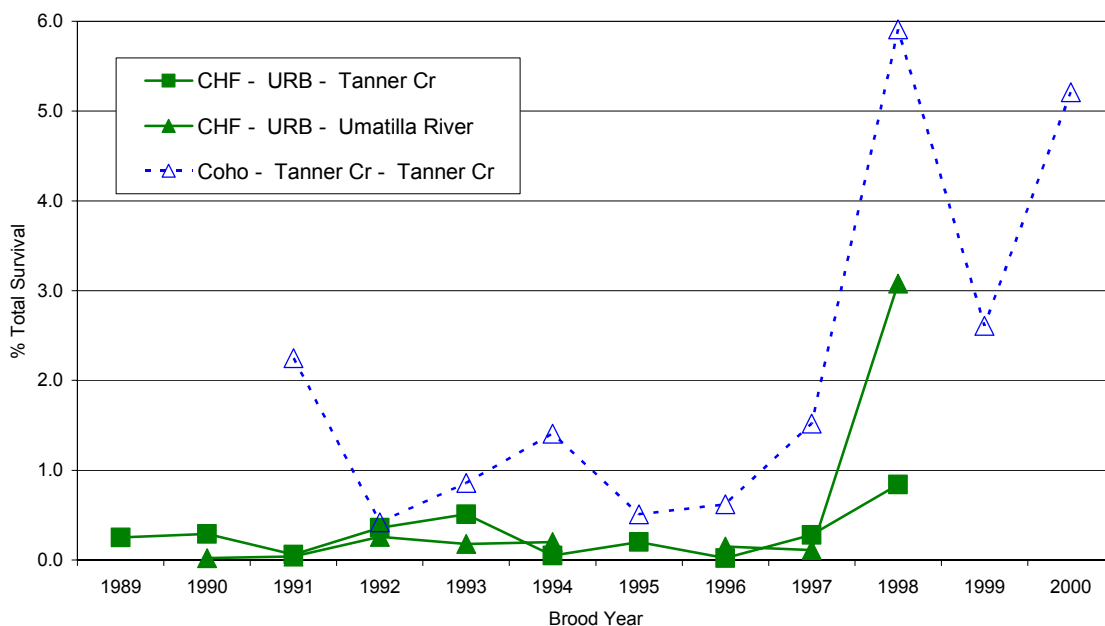

Figure 9. Percent survival by brood year for Bonneville Hatchery programs. URB = Up-River Bright stock.

Oxbow Hatchery

Oxbow Hatchery is located on the Columbia River 2 miles east of Cascade Locks off Highway 84. Oxbow Hatchery rears coho and spring chinook salmon. Coho reared by Oxbow Hatchery are released at Tanner Creek, Youngs Bay, or Umatilla River after acclimation and/or extended rearing. For results from these programs see the Bonneville, CEDC, and Cascade discussions above. The spring chinook from Oxbow are transferred to Clackamas Hatchery for rearing and release, results are reported under the Clackamas Hatchery section. Wahkeena Pond, located near Multnomah Falls State Park off Highway 84 was operated as a coho rearing satellite of Oxbow Hatchery through the 1992 brood. Release and recovery data for Wahkeena Pond CWT coho is reported in Appendix A. Wahkeena Pond is now being developed as a public fishing area instead of a hatchery rearing facility.

Round Butte Hatchery

Round Butte Hatchery is located at the base of Round Butte Dam on the Deschutes River east of Madras. Round Butte Hatchery rears and releases spring chinook, summer steelhead and brown trout. The summer steelhead and brown trout released from Round Butte Hatchery have not been coded-wire tagged for evaluation.

Percent survival for the 1989 to 1998 brood Deschutes River stock spring chinook released in the Deschutes River averaged 0.54%, and ranged from 0.08% to 1.96% (Table 6). Survival generally declined from the 1989 to 1996 broods, but has increased substantially since then (Figure 10). The very few ocean recoveries of Round Butte Hatchery spring chinook were in Oregon and Washington Coast fisheries (Appendix A). Freshwater recoveries were mainly hatchery returns, with freshwater catch (sport, gillnet, and tribal subsistence/ceremonial combined) accounting for about 36% of the total average freshwater recoveries (Table 10).

There are only 6 brood years of data available for Deschutes River stock spring chinook released in the West Fork Hood River (1991, and 1994 to 1998). Percent survival for these brood years averaged 0.17%, and ranged from 0.00% to 0.61% (Table 6). There have been very few ocean recoveries for these fish (Appendix A). Freshwater recoveries were about 38% at hatcheries and 63% in sport and gillnet catch, mostly above Bonneville (Table 10).

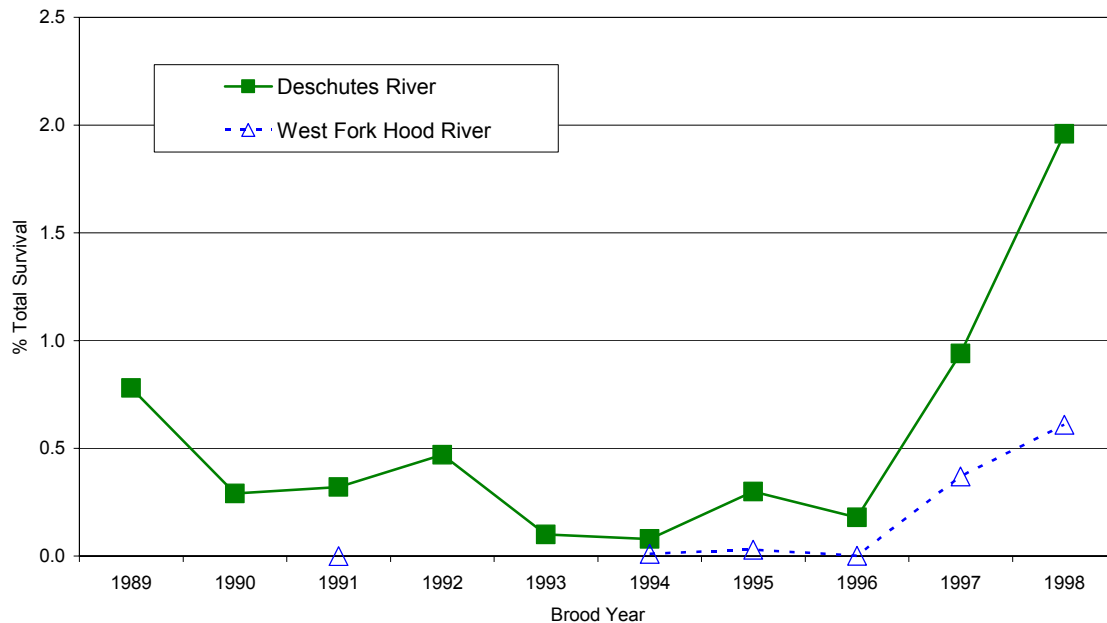

Figure 10. Percent survival by brood year for Round Butte Hatchery programs.

Oak Springs Hatchery

Oak Springs Hatchery is located on the Deschutes River 3 miles north of Maupin. Oak Springs Hatchery rears and releases summer steelhead, winter steelhead, and rainbow trout. The rainbow trout have not been coded-wire tagged for evaluation.

Average percent survival of the 1993 to 1999 brood Hood River stock winter steelhead reared at Oak Springs and released in East Fork Hood River was 0.32%, and ranged from 0.08% to 0.47% (Table 7). There were only freshwater recoveries for this group, which were mainly in freshwater sport fisheries (Appendix A).

Wizard Falls Hatchery

Wizard Falls Hatchery is located on the Metolius River 2 miles north of Camp Sherman off Highway 20. Wizard Falls Hatchery rears and releases Atlantic and kokanee salmon, brown, brook and rainbow trout. None of these fish have been coded-wire tagged for evaluation.

Fall River Hatchery

Fall River Hatchery is located on Fall River, a tributary of the Deschutes River southeast of Bend. Fall River Hatchery rears and releases cutthroat, brook, and rainbow trout. None of these fish have been coded-wire tagged for evaluation.

Umatilla Hatchery

Umatilla Hatchery, constructed in 1990, is located on the Columbia River adjacent to Irrigon Hatchery. Umatilla Hatchery rears up-river bright fall chinook, Carson stock spring chinook, and summer steelhead trout. Starting with the 1991 brood year, Umatilla Hatchery took over production of spring and fall chinook salmon for the Umatilla River from Irrigon Hatchery, and production of summer steelhead for the Umatilla River from Oak Spring Hatchery.

Percent survival of the 1991 to 1997 brood years of Umatilla Hatchery up-river bright stock fall chinook averaged 0.09%, and ranged from 0.00% to 0.32% (Table 3). Survival was generally very low through the 1997 brood but increased substantially with the 1998 brood year (Figure 11). Ocean catch was primarily in Alaska and British Columbia fisheries (Table 9, Appendix A). Freshwater recoveries were mainly hatchery returns, with above Bonneville Dam gillnet catch accounting for 50% of the total gillnet recoveries (Table 10).

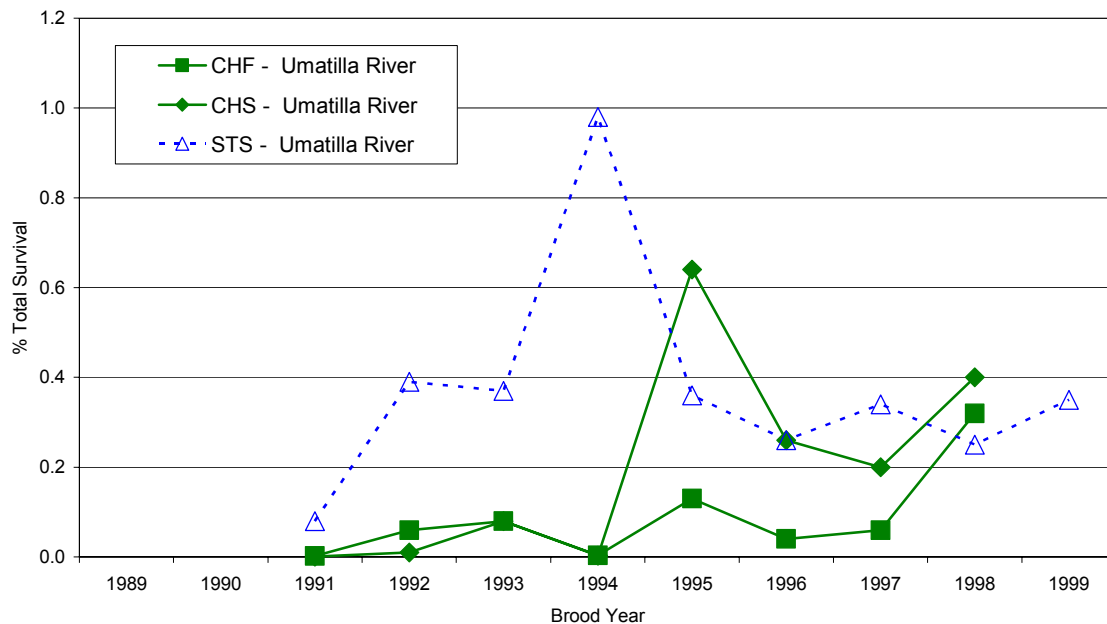

Figure 11. Percent survival by brood year for Umatilla Hatchery programs.

Percent survival of the 1991 to 1998 brood years of Umatilla Hatchery Carson stock spring chinook averaged 0.20%, and ranged from 0.00% to 0.64% (Table 6). Survival was consistently below 0.1% until the 1995 brood year which jumped to 0.64% (Figure 11). The 12 ocean recoveries were in; Alaska (2), Washington (2), Oregon (2), and California (6) fisheries (Appendix A). Freshwater recoveries were mainly hatchery returns, with recoveries on spawning grounds accounting for 30% of the total average freshwater recoveries (Table 10).

Percent survival of the 1991 to 1999 brood years of Umatilla Hatchery summer steelhead averaged 0.38%, and ranged from 0.08% to 0.98% (Table 7). Survival was between 0.25% and 0.40% except for the 1991 and 1994 brood years (Table 7 and Figure 11). The one ocean recovery was in a North Central British Columbia fishery (Appendix A). Freshwater recoveries were mainly hatchery returns, with catch (freshwater sport, and above Bonneville Dam gillnet) accounting for 34% of the total average freshwater recoveries (Table 10).

Irrigon Hatchery

Irrigon Hatchery is located on the Columbia River off Highway 730 near Irrigon. Irrigon rears and releases summer steelhead and rainbow trout. Starting with the 1991 brood year production of spring and fall chinook salmon for the Umatilla River was taken over by the new Umatilla Hatchery. Release and recovery data for Irrigon Hatchery fall and spring chinook salmon is reported in Appendix A.

The 1990 to 1999 brood years Imnaha River stock summer steelhead reared at Irrigon Hatchery and released in Little Sheep Creek averaged 0.38% percent survival, and ranged from 0.01% to 1.04% (Table 7). Survival was generally between 0.2% and 0.5% except for one year at 1.0% followed 1 year at 0.01% (Figure 12). The two ocean recoveries were in British Columbia fisheries (Appendix A). Freshwater recoveries were mainly hatchery returns, with catch accounting for 45% of the total average freshwater recoveries (Table 10).

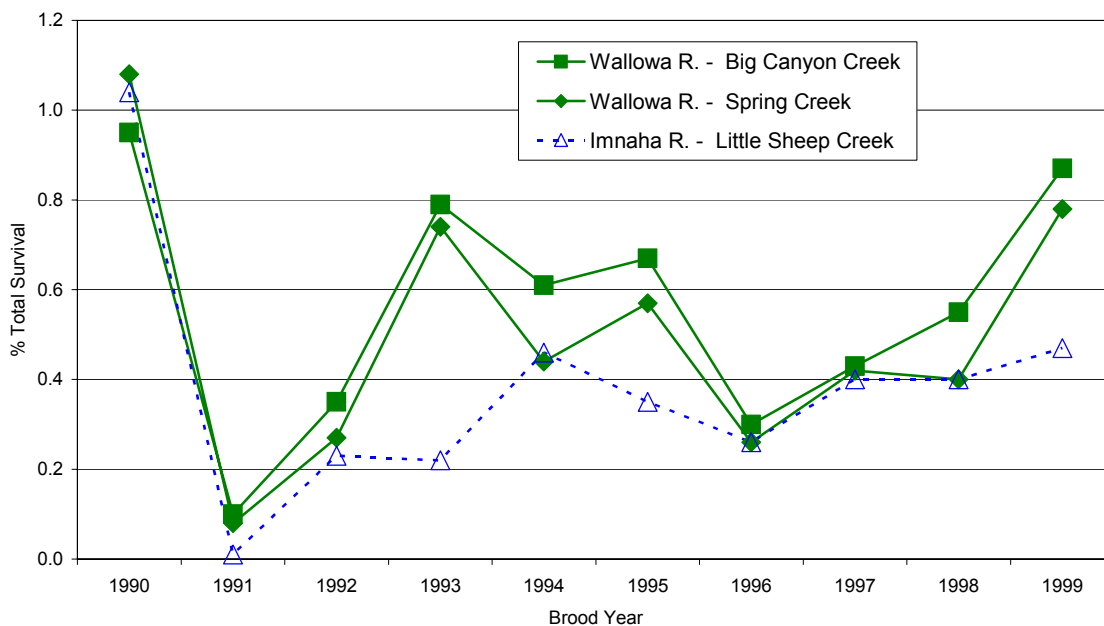

Figure 12. Percent survival by brood year for Irrigon and Wallowa hatchery summer steelhead programs.

Lookingglass Hatchery

Lookingglass Hatchery is located on Lookingglass Creek, a tributary to the Grande Ronde River north of Elgin. Lookingglass Hatchery rears and releases spring chinook salmon. In recent years Lookingglass Hatchery has begun a spring chinook captive broodstock program, based on wild fingerlings collected in the Grande Ronde Basin.

Percent survival of the 1989 to 1998 brood years of Rapid River stock spring chinook released in Lookingglass Creek averaged 0.13%, and ranged from 0.03% to 0.33% (Table 6). Survival was consistently 0.1% or below for 1990 to 1994 broods, increased for the 1995 to 1997 broods then declined to less than 0.1% for the 1998 brood year (Figure 13). The eight ocean recoveries were in Alaska (5) and Oregon (3) fisheries (Appendix A). Hatchery returns accounted for 77% of the total average freshwater recoveries (Table 10).

Percent survival of the 1989 to 1998 brood years of Imnaha stock spring chinook released in Imnaha River averaged 0.19%, and ranged from 0.01% to 0.49% (Table 6). Survival was about 0.1% or below for 1989 to 1994 broods, then increased beginning with the 1995 brood (Figure 13). The 21 ocean recoveries were in Oregon (18) and California (3) fisheries (Appendix A). Freshwater recoveries were mainly hatchery returns, with recoveries on spawning grounds accounting for 28% of the total average freshwater recoveries (Table 10).

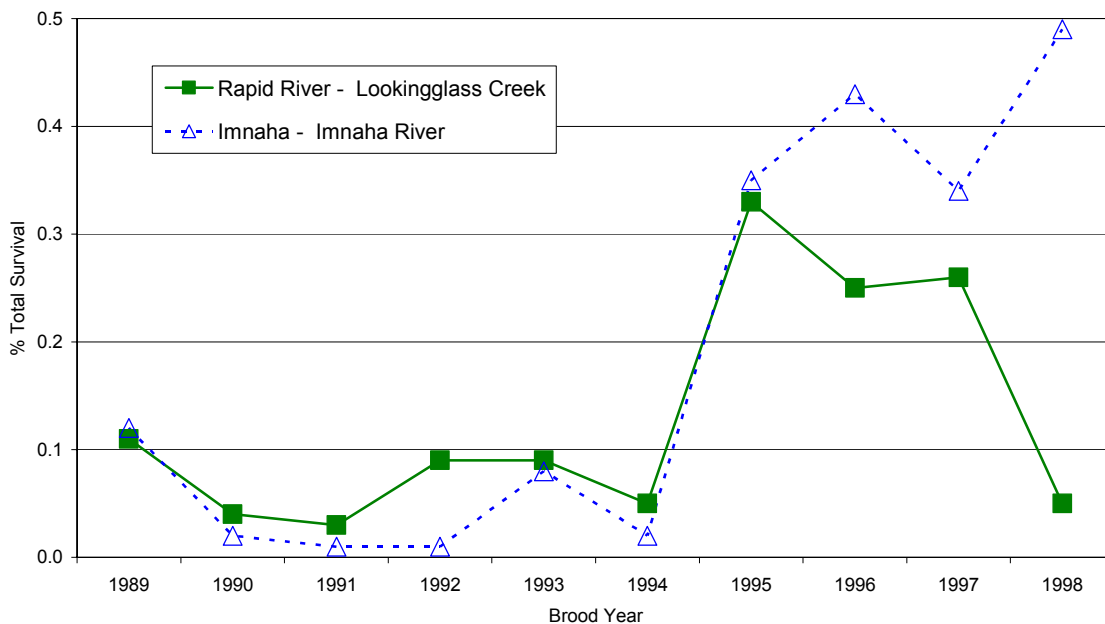

Figure 13. Percent survival by brood year for Lookingglass Hatchery spring chinook programs.

Wallowa Hatchery

Wallowa Hatchery is located on the Wallowa River near Enterprise. The Wallowa Hatchery rears and releases summer steelhead and rainbow trout. The rainbow trout have not been tagged for evaluation.

The 1990 to 1999 brood years Wallowa stock summer steelhead reared at Irrigon and Wallowa hatcheries and released in Big Canyon Creek averaged 0.56% survival, and ranged from 0.10% to 0.95 (Table 7). Survival was variable for the first 4 brood years (1990 to 1993), declined from the 1993 to 1996 brood years, and has increased since then (Figure 12). The 5 ocean recoveries were in British Columbia (4) and Oregon (1) fisheries (Appendix A). Freshwater recoveries were mainly in fisheries (sport and above Bonneville Dam gillnet catch), with hatchery returns accounting for 41% of the total average freshwater recoveries (Table 10).

The 1990 to 1999 brood years Wallowa stock summer steelhead reared at Irrigon, acclimated at Wallowa Hatchery and released in Spring Creek averaged 0.50% survival, and ranged from 0.08% to 1.08% (Table 7). Survival was variable for the 1990 through 1993 brood years, declined from the 1993 to 1996 brood years, and has increased since then (Figure 12). The six ocean recoveries were in Alaska (1), British Columbia (3), and Oregon (2) fisheries (Appendix A). Freshwater recoveries were mainly in fisheries (sport and above Bonneville Dam gillnet catch), with hatchery returns accounting for 44% of the total average freshwater recoveries (Table 10).
